List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING APRIL 25, 1893.

496,293.—WHEEL FOR SINGLE-TRACK RAILROAD—J. Burt, Tres Pinos, Cal.	
496,187.—IRRIGATING SYSTEM—B. O. Clark, Pasadena, Cal.	
496,188.—ELEVATED CABLE RAILWAY—L. F. Cook, Tacoma, Wash.	
496,189.—ELEVATED CABLE RAILWAY—L. F. Cook, Tacoma, Wash.	
496,046.—CREMATORY—D. F. Donegan, Los Angeles, Cal.	
496,248.—CHIN REST FOR HORSES—G. T. Duncan, Tacoma, Wash.	
496,301.—TAP AND FAUCET—Mattie Z. Farrington, S. F.	
496,355.—VEHICLE WRENCH—D. H. Fansl, Stockton, Cal.	
496,118.—DOUBLE-LAP PIPE—C. S. Hamlin, Los Angeles, Cal.	
496,311.—HARVESTER—Benj. Holt, Stockton, Cal.	
496,262.—LUBRICATOR—B. F. Howard, Sheep Ranch, Cal.	
495,979.—PIANO-FORTE ATTACHMENT—F. W. Kringel, Los Angeles, Cal.	
496,319.—TRACE BOOKLE—O. Mallory, Auburn, Cal.	
496,269.—PENCIL HOLDER AND SHARPENER—R. Mazza, San Leandro, Cal.	
496,270.—CAR VENTILATOR—T. L. Merrill, Oakland, Cal.	
495,991.—PRESERVING TIMBER—P. Murray, Seattle, Wash.	
496,325.—AXLE LUBRICATOR—A. W. Sanborn, S. F.	
496,235.—SMELTING FURNACE—Smith & Brewer, S. F.	
496,238.—MUSICAL INSTRUMENT—A. P. Venen, Seattle, Wash.	
496,022.—STONE-MOLDING MACHINE—W. B. Ward, Los Angeles, Cal.	
496,239.—WATER GATE—C. H. Watson, Riverside, Cal.	

The following brief list by telegram, for May 2, will appear more complete on receipt of mail advices:

California—Daniel Best, San Leandro, two patents, gas engine motor for cars and gas engine igniter; Ephraim Chaquette, San Francisco, bolt or rod cutter; Jabez F. Cowdery, San Francisco, fire extinguisher for railway car heaters and lights; William A. Duesbury, San Francisco, label for Elmore, Biggs, pump; Stephen C. Houghton, San Francisco, fare register; Augustus Knudsen, San Francisco, steam engine; Isaac W. Lord, Cucamonga, fruit picker; Joseph P. Magney and R. Lietz, San Francisco, knob attachment; John R. McCurdy, Los Angeles, stand attachment for bicycles; Axel Wernsberg and J. G. Egan, San Diego, running gear; Sanders, Portland, electrode for arc lamps and electric arc lamp; Alfred C. Sanford, The Dalles, castor axle and wheel.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

NOTICE OF ASSESSMENT.

Gould and Curry Silver Mining Company. Location of principal place of business, San Francisco, California. Location of works, Virginia, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 11th day of April, 1893, an assessment (No. 71) of Twenty-five Cents (25c) per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 69 Nevada Block, 309 Montgomery street, San Francisco, California.

Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1893, will be delinquent, and advertised for sale at public auction; and unless payment is made before, will be sold on TUESDAY, the 6th day of June, 1893, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.

By order of the Board of Trustees.

ALFRED D. DUNBROW, Secretary.

Office—No. 69 Nevada Block, 309 Montgomery street, San Francisco, California.

FOR SALE.

One Ohmen's 12 x 12 Automatic Engine; best style in use. Also, 1 Boiler 43 in. x 16 ft. Both nearly new. Apply to J. W. QUICK, 221 First St., (Top Floor) San Francisco, Cal.

MINING AND SCIENTIFIC PRESS.

Concentrating and Concentrators.

The mechanical concentration of ores is based entirely on the differences of the specific gravity of their component parts; and one of the most important points to be considered and accomplished in the treatment of gold-bearing ores is, "the nearest approach to a separation of the silicious and gangue matter from the residual mineralogical contents of the ores," whatever difference of specific gravity may exist.

Many devices have been conceived, invented and introduced to the notice of mining men for the purpose of effecting the proper separation of the pyritous matters contained within the ores from the accompanying gangue, and we here present an electro illustrating the recently improved form of "Triumph" concentrator, which shows the improvements which have been introduced into its construction, by which many advantages are gained over other forms of vanners, vanning machines or concentrators.

These advantages are obtained by reason of the fact, as will be observed from the cut, that crank-shaft is now placed and fitted at the head of the concentrator, clear of the belt and in direct view of the operator or attendant. This, of course, greatly facilitates the oiling of the bearings of the shaft and connecting-rod and precludes the possibility of any sand or detritus passing over the belt from reaching or getting into the bearings.

The forms of the bearings and as well of the connecting-rod brasses have also been very much improved, making them stronger, simpler and more easy of adjustment. Important improvements have also been made in the feed-screw and quadrant for regulating the belt, with the view of making all of the parts of the machine stronger, more accessible and as easy of regulation as is possible.

The Joshua Hendy Machine Works, of No. 51 Fremont street, this city, are the builders and controllers of the form, as herein presented, and have one set up ready for operation at their office; and a representative of those works informs us that they will be pleased to have mining and mill men examine the improved machine.

THE schooner Czarina, brings the information that some of the miners working in the Apollo mines, on Unga island, Alaska, had a disagreement among themselves and were discharged. Some of the miners left here last January on the steamer Dora, on that steamer's mid-winter trip to Alaska. The discharged miners circulated stories at Sand Point that the high grade of ore discovered a year ago at the mines had fallen off.

"THE MODERN TRAVELING CRANE" is the title of a pamphlet issued by Wm. Sellers & Co., Philadelphia. It contains a paper by Alexander E. Outerbridge Jr., which was read before the Franklin Institute. There is a great deal in this of interest to foundrymen.

California Manganese.

Manganese is a "pockety" sort of substance to mine, the deposits being irregular and not to be counted on as to extent. It is produced in this State in a small way, mainly for use in the manufacture of chlorine for the chlorination of auriferous sulphurets. The total amount of manganese produced in California up to the close of 1891 was 7144 tons. In the latter year it all came from two mines, one in Alameda and the other in San Joaquin county. The amount yielded in 1891 was 705 tons worth \$3830 or \$5.44 per ton. The general average of the 23,416 tons manganese ores produced in the United States in that year was \$10.21 per ton. There is indication of a growing scarcity in this country of high-grade ores such as are classed as manganese ores proper.

Virginia is the leading producer of manganese in the United States, yet it only produced 16,348 tons in 1891. Georgia comes second with 3575 tons, and Arkansas next

IMPROVED FORM OF "TRIUMPH" ORE CONCENTRATOR.

with 1650 tons valued at \$11 per ton. The average value of the Virginia ores was \$11.17 per ton. Most of this comes from the group of mines at Oromora. Manganese has been found in several counties of California, but the deposits are not steadily worked and little prospecting is done for the mineral. What is found is not of very high grade and its value is therefore low as compared with the ores of other States.

EX-SENATOR O. W. CROSS and Hon. James A. Hall of Santa Cruz, who have been conducting a law partnership in San Francisco for some years, and are well known in mining litigation, have organized a new law firm by taking into partnership Senator Tirey L. Ford of Downieville and Hon. Frank P. Kelly, ex-District Attorney of Los Angeles county. Senator Ford, however, will continue to reside at Downieville, and will attend to all business the firm may have in the mining counties.

THE next western gathering will be the western slope congress at Montrose June 21. This will be followed by the southwestern miners' silver congress at Silver City, N. M., on July 4th; the mining congress at Salt Lake city on September 11th, and the irrigation congress at Los Angeles, Cal., on October 10th. All of these gatherings will be of large influence in advancing western interests and concentrating western opinion.

The State Debris Commission.

It is to be hoped that Governor Markham will, in his selection of a State Debris Commission under the Ford Act, exercise great care and discretion. Although the law calls for a "competent civil engineer," a large proportion of the civil engineers would be of small service, simply because they lack the technical knowledge of mining matters that this official should have. As far as mere engineering knowledge is concerned, such as that required for the construction of dams, and to make calculations for flow of water, etc., the Government Debris Commission are perfectly well equipped and scarcely need any consultation and advice with a State Debris Commissioner. This latter official is to examine and pass upon the merits of works for the impounding of mining debris, or rather upon the plans and specifications for their construction. There is something needed in all this beyond the mere knowledge of how to build a dam.

A civil and mining engineer should be selected for this position. Any man filling this office without some intimate knowledge of hydraulic mining would be mainly interested in drawing his salary, and would be of no use to the U. S. Engineers forming the Government Debris Commission.

If the Governor of the State will appoint as Commissioner some expert engineer who is familiar with the conditions relating to the hydraulic mining industry, the two Commissions will work in harmony

and accomplish a great deal more than if the man appointed has limited his experience to some other branch of engineering. Mere politics should not count in this appointment. There are several competent men who would accept the position and do their duty in a satisfactory manner. The Government Commission will need advice and assistance in the mining features, and, as mining debris and mining operations form the basis of all their work, the State ought to provide the mining engineer.

Some of the valley counties are already asking that the Commissioner should be appointed from their midst, but putting an anti-debris man in as a debris commissioner seems absurd, to say the least. We need a man with mining experience and knowledge to fill the position satisfactorily. This work is to be mainly advisory in any event and he ought to be expert enough to give advice that will be of some value. The term of office is only four years for this Commissioner and it would take ordinary civil engineers that long to become expert in the mining features. Governor Markham has by words and acts shown his friendship to the miners of this State, and he can still further add to their gratitude by appointing as Debris Commissioner a skilled, expert and conservative mining engineer.

THE export of California wines by sea in April were 1474 cases and 354,920 gallons, valued at \$172,133.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Improved Form of "Triumph" Ore Concentrator, 289.
 EDITORIALS.—Concentrating and Concentrators; California Manganeses; The State Debris Commission; Miscellaneous; 289. Comment; Working Comstock Mill Tailings; Magnetic Separation of Ores, 290.
 MISCELLANEOUS.—Foundry Notes; Industrial Notes, 291. The New State Mining Bureau Law; The Real Significance of the World's Fair, 292.
 CORRESPONDENCE.—The Ideal Currency; The Double Standard; Free Silver Coinage and National Banks, 293. Churntown District, Shasta County, 294.
 MISCELLANEOUS.—New Estimation Method for Manganese; Vastness of the World's Fair; Mail for the World's Fair, 294.
 MECHANICAL PROGRESS.—Cost of Operating Cable Roads; Sawing Lumber in Mendocino County; Glass Brick, 296.
 SCIENTIFIC PROGRESS.—Matter Held in Suspension in Moving Water; Copper from Birds; Evolution in Artificial Stone; Diamondiferous Native Iron, Etc.; A New German Explosive, 298.
 ELECTRICITY.—Electric Boats for the World's Fair; Storage Battery Cars on Second Avenue; Electro-Deposition of Copper, 298.
 USEFUL INFORMATION.—What Constitutes Millwork; Unloaded Air; Lightning Rods on Ships; Treatment of Low-Grade Salicious Ores; Making Glass Eyes, 298.
 MINING SUMMARY.—From the Various Counties of California, Nevada and other Pacific States and Territories, 301-302.
 MARKET REPORTS.—Eastern and Local Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings; Assessments, Dividends, etc., 303.

Comment.

The newspapers have stated that the Haywards electric road will run freight cars at night to bring the fruit products of Alameda county to market. This the company deny, but it would seem a sensible proposition and one which might be profitable. In cities like Oakland, San Jose, Fresno and other places with a surrounding agricultural population, where electric roads run for miles out into the country, the utilization of the roads for freight at night would seem entirely feasible. It would certainly aid in the development of the outside tracts. Generally speaking, our country roads are poor, and great expense is entailed on the producers in bringing their products to the town or railroad. If five or ten miles of team haulage could be saved it would be quite an item. In such a road as will run from Santa Clara to Saratoga, for instance, there ought to be more in the freight than in the passenger business. The Haywards road from Oakland is about 13 miles long and runs through a rich fruit and vegetable region. If freight was carried on this road at certain hours, the farmers for miles on both sides would have a great advantage in marketing their products rapidly.

Californians have rather had the conceit taken out of them by the comments which come from Chicago relative to the State's exhibits at the World's Fair. It was imagined that because California had put up more money for the fair than any other State, except Illinois and New York, its exhibit would excel the others. With \$600,000 at command, a magnificent show should have been made, but thus far it seems to be unsatisfactory. The newspaper correspondents accord the exhibit no praise, and those persons who have returned confess they were ashamed of the backwardness of affairs in the California building. A palm tree and the figure of a horse made in prunes seem to have been the only things which have attracted special attention. Other States excel us in horticultural and mining displays, our own two specialties. We expected great praise, but thus far have received mainly criticism, even from our own people. All this is greatly to be regretted, and it is plain that there has been blundering and incapacity on the part of some in charge of the affair. It will doubtless be found that too much money has been paid out for salaries and not enough in the practical features of collecting the products to be exhibited. We know this to be the case in the mining department and will not be surprised to hear the same complaint in connection with other divisions. It is not too late, however, to remedy defects, and the criticisms made public should have an immediate beneficial effect. Already the officials of the State Mining Bureau have sent an additional supply of

the ores from which gold is obtained, because one of the correspondents said there were none to speak of in the California mineral exhibit. But the Mining Bureau is not responsible for any defects. Part of its collection forms the bulk of the California mineral display at the fair. Had the commissioners and superintendent showed ordinary energy and activity, we ought to have made a more complete mineral display than any State in the Union.

The San Francisco Board of Supervisors now in office seem to be trying to educate the street contractors up to the idea that they must carry out the specifications and do the work as agreed upon. Men who have been taking bitumen-pavement contracts for 17 and 18 cents a cubic foot, when the actual cost for proper work was 23 cents, will have to quit their former customs. The Street Superintendent no longer looks at the surface of a completed street before accepting it. The Street Committee go with him and have men dig up two feet square of the bitumen, and then dig into the concrete foundation. If it is found that there are six inches of good concrete and two inches of bitumen, the street is accepted; otherwise not. No portions of blocks or crossings will hereafter be accepted unless portions are dug up and examined. All this is a move in the right direction. The next thing to do is to enforce an ordinance against heavily-laden wagons with narrow tires, so as to save the streets when they are put in order. This is done in other cities and should be here. There is a decided tendency all over the country for better streets and better roads. The methods of making and maintaining them are well known, but the failure to apply these methods is the trouble. Our local Supervisors have started on the right track and it is to be hoped they will continue their good work.

As the big hydraulic mines in the upper portion of the State are being put in order for work under the provisions of the Caminetti Act, the Anti-Debris Association are turning their attention to the small claims in Nevada, Sierra and Plumas counties, and enjoining many which were being operated on a small scale. There are many of these little claims, owned by individuals, the work on which does little or no harm; still they are being enjoined. So, for the present, at least, the Anti-Debris Association people are getting the advantage under the operation of the new law. The miners' turn will come, however, and only a little patience is needed. When the Government Commission is organized a license to mine may be procured readily in most of these instances, and then operations may be resumed without reference to the Anti-Debris Association or "spies." Where there are a number of these smaller mines draining into one canyon or stream, a single dam, to be paid for jointly, will give all a chance to work. While, therefore, injunctions may be pretty thick just now, they will in time be dissolved and the mines be permitted to work. A license from the Government Commission, once secured, will relieve the miners from future persecution, compliance with the law being adhered to.

Some men who own a farm on the bank of the Sacramento river, above Redding, Shasta county, have rigged up a crude dredging machine and are represented as making money by getting the gold in the gravel found at the bottom of the river. A small steam engine serves to operate the dredge and the windlass for moving the boat. In some instances two men have averaged \$20 a day for a week at a time; at other times they cannot get gravel in paying quantities. In early days there were rich diggings in the many creeks emptying into the Sacramento above Redding, and there should be plenty of gold in the bed of the main stream. A new engine has been bought for the dredging boat referred to, and more systematic efforts will be made to hunt for rich spots. This is the first instance in our recollection where any profit has been made in dredging a California river bed. The plan has been tried a number of times and on a large scale, but each attempt has been a failure. While the hucksters brought up gravel, sand and rocks, the proportion of gold has been too small. However, most of the attempts have been on rivers the beds of which were covered with sand and debris from mining operations. The upper Sacramento would appear to be the best place for this kind of mining. River dredging for gold is carried on successfully in some of the Australian colonies, but, as stated, we have never made a success of it here, with the exception of the instance noted.

From several of the counties come reports of the increased interest in quartz mining this spring. A fresh impetus was to be expected this year in California because this State is the principal gold-producer of the Union, yielding annually more than four times any other one. The "black-eye" given to silver mining by the decline in value of the product has driven many out of that business who will go into gold mining. It cannot be said,

however, that many San Francisco men are making investments in these properties; the people who are doing this are from other States and are in a better position to recognize the value of our quartz properties than we are ourselves. That is, we do not properly appreciate the advantages in mining that is right at our doors; but mining men from other sections, when once they investigate, do not take long to decide. But we need capital to develop our prospects, and do not much care where it comes from, so that it does come.

Owners of "prospects" should remember that the other fellow must take some chances if he buys their claims. Therefore the prices asked ought to be less than what the whole mine is worth after it is developed. A claim may develop into a mine, and yet again it may amount to nothing more than a hole in the ground. These chances have to be taken by the man who buys a prospect and should be taken fully into consideration by those who have such claims to sell. It is foolish, therefore, to put the price of a developed claim on to what is merely a prospect. But it is doing this which keeps miners poor and keeps investors away. As there appears just now a good chance to sell "gold prospects" in this State, it is to be hoped their owners will be reasonable and not demand such exorbitant prices as to discourage the buyers.

Magnetic Separation of Ores.

Along the Rhode Island shore the iron sands of the beach are treated by passing them over magnetic separators and a small quantity of concentrated iron ore is then produced and sold. There are on the ocean beaches of this State vast quantities of magnetic iron sands, but few attempts have been made to utilize them. Some ten years or so ago smelting works for their reduction were put up at Sausalito, but the venture was not a success. At that time magnetic separation was not thought of. Magnetic separators have been in use since 1852, but it is only within late years that this system has attracted much attention. Although the forms of magnetic separators vary, they may be classed under three general heads: (1) Altering the trajectory of falling material by introducing the attraction of a magnet, to draw the magnetic portion away from the non-magnetic.

(2) Feeding the ore to a revolving drum or drums, in which is a magnet core, the shells of the drum being either of alternate magnetic and non-magnetic strips or entirely of magnetic or non-magnetic material. In some of these drums the magnet core is wound so as to exert a constant polarity, in others a series of magnets of alternate polarity compose the core, and in some, opposite drums are of opposite polarity. When two drums are used, they are placed so as to revolve toward each other, the ore passing between them, or they are arranged tandem, the drums revolving in the same direction, but sometimes at different speeds and with different degrees of magnetic force, so that the ore fed from one drum to the other receives successive treatment. Machines are also arranged with more than two drums.

(3) Belt machines in which the ore is fed to a belt or series of belts passing under or over magnets or magnetic drums, the machines working sometimes in water and sometimes dry. In some of the machines the polarity is maintained continuously by means of pole pieces; in others the material is constantly submitted to magnets of alternate polarity, the belts being placed so as to run either vertically, horizontally, or on an incline, according as the conditions require.

Of these different classes, there are now in actual operation the following: Six of Class 1, 29 of Class two, and 27 of Class 3. These are used either at the mines to enrich the ore, at steel works and rolling mills to remove the magnetic particles from slag and dirt, to separate iron ore from pottery clay or from emery—and, in one instance, iron ore occurring as a hematite with zinc ore is treated in a roasting furnace after being comminuted, and, becoming magnetic, can be separated.

Mr. John Birkinbine, in the "Mineral Resources" of the U. S. Geological Survey, states that the principal magnetic separator plants are those of Messrs. Witherhees, Sherman & Co., at Mineville, New York, who constructed the first large plant operated entirely with magnetic separators, and made a number of experiments with various machines. There are also large magnetic separating plants at the Orono mines, at Clover Hill, and at the Tilly Foster mine, near Brewster, New York; at the Magnetic Iron Ore Company's works at Little River, New York, and another at the Ogden mine, New Jersey. In addition to the extensive plant which Mr. Edison has at the Ogden mine, he also put up plants at Humboldt, Michigan, and Bechtelsville, Pennsylvania, both of which were destroyed by fire. In addition to those plants mentioned, there are smaller ones at Michigamme, Michigan, two in New Jersey, two in Pennsylvania, and one each in

Virginia and North Carolina. There is apparently a wide field for magnetic separation, and doubtless experiments will be made in California in time.

Working Comstock Mill Tailings.

The Comstock mines last year turned out 104,058 tons of ore, the gross yield or value of which was \$1,560,923. The actual cost of extracting was \$1,206,965, and transportation \$17,704. The actual cost of reduction by free milling was \$644,517, making the total cost \$1,869,188. These figures are reported by the county auditor to the State comptroller for revenue purposes. The mills worked also 27,793 tons of tailings, the gross yield of which was \$91,467. The cost of extraction was \$77,915. The profit was \$14,515. In milling the ore a larger proportion of the silver than the gold passes away in tailings. The slimes of these tailings assay in gold and silver proportionately about the same as the original ore, but the heavier sands and sulphurets contain about one part of gold to three parts of silver. The run of promiscuous slimes and tailings gives an average reduction result of 66½ per cent silver to 33½ per cent gold. The earlier ore workings were naturally experimental and unequal and the saving and working of the sandy sulphurets and slime render the expressive name of "tailings" still more so.

These figures are taken from a chapter by Alf. Doten in the latest Report of the Director of the U. S. Mint. There is no doubt that in some of the cruder experimental processes, at first adopted, a larger proportion of the precious metal contained in the ore escaped in the tailings than has since. Some, however, in the form of sandy sulphurets were caught in blanket sluices and reservoirs, but much of the richer and lighter chlorides, etc., as well as sulphurets, amalgam and quicksilver, were washed away down the Carson river. Dredging operations in the river have not paid a profit. Some large deposits and reserves of old tailings are still being worked at a profit, but quite a falling off in that industry is caused principally by a more careful and effective operation of the mills and these tailings sluices allowing but a comparatively small percentage to escape. Between 1871 and 1893 a total of 2,675,825 tons of Comstock tailings have been worked. The gross yield has been \$13,179,947; cost of extraction, reduction, etc., \$10,672,386; net yield in value for taxation, \$2,747,671; total profit, \$2,520,058.

Foundry Notes.

The contract has been let for a large four-story brick building on First and Natoma, and the old wooden building that has long stood upon that site has been torn down to give way for the new structure. The Pacific Metal Works are the owners.

A FORTY-TON GASOLINE ENGINE SCHOONER, built at Benicia for Justinian Caire and designed to run between Santa Rosa island and Santa Barbara, has been brought down from Turner's yard and will fit out at Mission pier 1 for her trip south.

The new steam schooner *Excelsior*, which recently arrived here from Eureka, has gone to Folsom-street wharf have her boilers put in, after which she will be towed to the Fulton Iron Works at Harbor View to receive her engines. The *Excelsior* is the largest steam schooner on the coast, having a length of over 200 feet; she is over 700 tons burden. She was built to run between Eureka and San Diego, and will be ready for sea by June 1st.

The British ship *Alcides*, which arrived last month from Newcastle, England, has discharged at Union-street pier, 290 steel plates for ship-building. The plates are 40 feet long, one-half inch thick, and of various widths. They are for the Union Iron Works to be used in the construction of vessels building there. The *Alcides* also has among her cargo 200 tons of steel shearings or clippings from large steel sheets which are consigned to the Judson Nail Works at Oakland.

The steamer *Arago* is at the Union Iron Works undergoing extensive alterations. Goodall, Perkins & Co., the new owners of the steamer, intend having cabins and passenger accommodations built on the *Arago* to correspond with those on the *Corona* and *Pomona*. The steamer *Arago* is 620 tons register and was built here in 1885. She was the first iron vessel built on this coast and was constructed at the Union Iron Works, an establishment which has since distinguished itself by work on large war vessels for the Government.

The San Francisco Tool Company has just shipped a very large centrifugal pump for drainage and reclamation purposes. This is the second sent from these machine works to the tule lands on the San Joaquin river within a few weeks. The first pump has a capacity of 10,000 to 15,000 gallons per minute, while the one on the road will pump 30,000 to 40,000 gallons per minute. The diameter of the discharge pipe in the smaller is 20 inches; in the larger 40 inches. The pump is strong and well made, on special designs adopted by these works. The Tool Company has made a specialty of this class of pumps, and has quite a number of them at work on the tule lands of the State.

The Olympic Club Salt Water Company, which has a franchise for selling salt water in this city and is now laying its supply and distributing pipes, is delayed in its work because the pipe does not come fast enough from the

manufacturers in Oregon. This is a San Francisco company, with San Francisco capital, intended to make its profits out of San Francisco people, yet it sends to Portland, Oregon, for the pipe used in its entire plant. This is not the kind of enterprise to be encouraged. There are several of the largest pipe-manufacturing concerns on the coast located in this city, and they ship it in all directions, yet our own people when wishing to buy go somewhere else to save a few dollars. The new Vallejo Water Works did the same thing, sending to Portland, Oregon, for pipe to save \$700 on a big contract. The Olympic Company might have been patriotic enough to buy their pipe if not in their own city at least in their own State.

Coast Industrial Notes.

LOCAL capitalists are making a move to erect a wool-scouring establishment in Reno.

THE exports of flour from San Francisco in April were 76,980 bbls of wheat, 536,561 cts.

BIGGS, Butte county, wants a fruit cannery, as there are thousands of acres of fruit trees of all varieties near the town.

NAPA voted bonds to the amount of \$27,000 for the building of Third-street bridge. The structure cost \$25,825.62 and is a useful ornament to the city.

In the year 1892 the Southern Pacific Railroad Company used 6,000,000 feet board measure of timber in repairs of track. Very few iron bridges have been built, as they are too costly.

THE 350-foot ocean wharf at Shelter cove went all to pieces the other day while the steamer *Emily* was landing her freight upon it. The wharf was the property of H. Dutard of this city.

DURING the month of April the total catch of the salmon canneries on the Columbia river was 78,124, or 24,038 cases. A comparison with the records of 1891 and 1892 shows that this is 32,624 more fish than were packed in April, 1892, and 17,101 less than in April, 1891.

THE new electric road from Oakland to Alameda is now completed and in operation. The officers of the company are: President, W. M. Rank; vice-president, Colonel F. H. Meyers; secretary, S. H. Bass; directors—E. S. Denison, W. H. Bailey, W. M. Rank, F. H. Meyers and S. H. Bass.

THE Uncle Sam quartz mine, (W. M. James, formerly of Sierra City, superintendent), says the *Redding Free Press*, is averaging \$30,000 monthly yields or \$1000 a day. The ore reserves there are said to be larger than those of any ledge in the State. Chlorination works are in full blast.

THE Carson river dredger was launched at Dayton last week. It has been building for a month under the supervision of Captain J. W. Hatch. The boat is eighty feet long and thirty feet wide. She was christened the *Pearson Halstead*. It is expected that it will recover the quicksilver from the river which was wasted by the mills.

IN traveling over the coast division Railroad Commissioner Beckman found about 900 men at work on the railroad extension between Santa Margarita and San Luis Obispo. There was also a large number of men working on the bridge crossing the Merced river in the San Joaquin valley. Cretaceous piling was being used for a foundation.

A SHIP was cleared from this port on Saturday with a cargo of wheat for Dunkirk, France. This is the first cargo of the kind from this port to a direct port in France for at least a full year. Some years, French dealers have operated extensively in this market, and many cargoes have been shipped to Havre, Dunkirk, or some other port in France.

JUDGE TORRANCE of the Superior Court at San Diego, has decided in favor of a mechanic's lien taking precedence over mortgage holders in the case of the Pacific Mutual Life Insurance Company of San Francisco vs. John C. Fisher et al., involving the priority of claims in the settlement of the Opera-house suit. The mechanic's lien amounts to about \$25,000.

ANOTHER application for a franchise to operate an arc and electric light system in Alameda was made to the Alameda City Trustees on Monday by W. M. Rank, F. H. Meyers and W. H. Chickering, the first two being the President and Vice-President respectively of the new electric street railroad company, which has established their power-house on Webster street.

THE election at Santa Rosa on the proposition to bond the city for the construction of new water works, to be owned by the city, was one of the hottest in Santa Rosa's history. The proposition was adopted. There were 981 votes cast, of which 730 were in favor of the proposition and 251 against. It is the intention of the city council to put in the pumping system known as the Wagner steam filter wells.

THE *Silver State* is informed that the smelter at the White Cloud copper mines, Lovelock, Nev., was started up last week and made a successful run. One hundred and five tons of ore were smelted in three days and a half, the result of the run being fifteen tons of matte. The smelter was closed down on account of running out of ore, but the force of miners has been increased and it will be started up again soon.

THERE is a movement among some of the business men of Red Bluff to raise money to build works for the manufacture of the Wise combined harvesters, one of the machines having just been built at the foundry at that place. There is wisdom in such a course, for if people of a town or city will manufacture the machinery they require it will keep money at home, give employment to labor and make business for the merchants and trades.

A DESPATCH from Los Angeles dated May 4th says: The Collector of the Port this morning received orders from the Secretary of the Treasury directing him to station

one of his deputies at Santa Monica, that being made a sub-port of entry to the customs district of Los Angeles. This is of great significance, as it places Santa Monica (Port Los Angeles) on an equal footing with San Pedro. This means that vessels from foreign ports can land at Santa Monica (Port Los Angeles) and discharge their cargoes.

THE San Francisco Slate Quarry, El Dorado county, has completed its preparations for operating the mine by machinery, and set it in motion. It comprises an air compressor which will be used in operating a channeling machine, drills and other appliances for getting the slate from the quarry. A small dynamo has also been set up at the mine and all the buildings will be lighted with electricity. The San Francisco Quarry has now better facilities for economical working than any other mine on the coast.

THE steamer *Noyo* arrived on May 5th from Fort Bragg with the fifth cigar-shaped raft brought to this port. The raft contains 1,500,000 feet of redwood logs, and was broken up during the day at the foot of Center street. The logs will be cut up at the Potrero sawmill, and the sawdust and slabs, which have a market value as well as the boards cut, saved. Lumber freights are \$3.50 and \$3 per 1000 feet. It is claimed that by the cigar shaped raft method, logs can be brought here for \$1 per 1000 feet, and that the sawdust and slabs, which are waste in a lumber district, can be made to pay the cost of bringing the logs here.

THE Pacific Iron and Nail Works of Oakland shut down last week and will remain closed for six weeks or two months. There are about 200 men employed by the company. This is the regular summer shut-down. President H. J. Sadler says: "We have a large stock of manufactured goods on hand. Prices for iron products are very low just now—indeed, lower than they have ever been; but in the East, just the same as here, there has been an overproduction, which accounts for the depression. I think this is the true reason for the ruling prices in the iron market, but the condition of the market has nothing to do with the closing of the works."

DURING the past few weeks there has been formulated at San Bernardino a plan to irrigate the largest tract of land in one body to be found in southern California. This will be accomplished by damming the Mojave river at Victor, creating an artificial lake nine miles long, three miles wide and 130 feet in depth, water sufficient to irrigate 200,000 acres of desert land. The Victor Reservoir Company has been quietly at work for some weeks securing options on land and water rights. Some wealthy Eastern men have taken stock in the company, and it is announced that contracts may be entered into at once for water rights. The water will be diverted upon Government land now unoccupied and subject to settlement and reclamation. It is estimated that the entire cost of construction will be less than a million dollars.

MARSHALL J. KINNEY, one of the oldest and most extensive salmon packers at Astoria, makes an important statement regarding the Alaska salmon industry. He says: "I consider the Bering Sea and Cook's Inlet will be the future field for the salmon industry. I think the pack of Northwestern Alaska will reach over 1,000,000 cases in less than five years. Half the salmon streams, as near as I can learn, are not even touched. When we have better railroad facilities to Astoria I expect the cold-storage and fresh-fish business on the lower Columbia and in Alaska will be simply enormous. Alaska is the coming field for the salmon industry, and fully expect that the production will double inside of five years. Mr. McKinney shows that the pack has increased from 36,000 cases in 1883 to over 480,000 cases in 1893. He says that the stores and gear sent north this year indicate that the Alaska cannerymen are preparing for the largest pack on record. He calculates that it will reach 800,000 cases."

THE Olympic Salt Water Co. of this city has leased for 20 years a large lot on Bush and Larkin streets. The company intends building a four-story brick structure to be used as a public salt-water bathing institution. One of the features of this building will be a magnificent swimming bath 200 feet long and 100 feet wide. Round the bath, overlooking the tank, there will be arranged a fine auditorium with seating capacity for from 2000 to 3000 people. In addition to the swimming tank there will be every kind of tub, medicated, Turkish, Russian, steam and electric baths. Out at the beach the foundations are being put in as rapidly as possible for the one-story brick steam pumping station. This establishment will have powerful compound engines capable of forcing the water into the salt-water mains all over the city. The contracts for the foundations, which will cost \$10,000, have been let, as also for the grading, engines, boilers and reservoir.

THE San Francisco MINING AND SCIENTIFIC PRESS of the 6th instant devoted a great deal of its space to the hydraulic mining cause. The PRESS is one of the best friends the hydraulic miners have, and its efforts in their behalf have been quite instrumental in bringing about the change of feeling throughout the State toward this process of mining. The paper is certainly entitled to the good will and support of the entire mining community.—Grass Valley Union.

THE official statement of gold in the Treasury for use, made to Secretary Carlisle at the Cabinet meeting, shows that the gold in the Treasury amounts to \$97,401,000; gold in transit, \$556,000; total, \$97,957,000. The total gold in the country, as estimated by the Treasury officials' circulation statement, aggregates \$613,000,000, of which \$518,000,000 is in circulation.

A MONTHLY PUBLICATION on "Popular Astronomy," mainly for amateurs, is to be issued by Wm. W. Payne, publisher of astronomy and astro-physics, Goodsell Observatory of Carleton College, Northfield, Minn.

The New State Mining Bureau Law.

An Act to provide for the establishment, maintenance, and support of a bureau, to be known as the State Mining Bureau, and for the appointment and duties of a Board of Trustees, to be known as the Board of Trustees of the State Mining Bureau, who shall have the direction, management, and control of said State Mining Bureau, and to provide for the appointment, duties, and compensation of a State Mineralogist, who shall perform the duties of his office, under the control, direction, and supervision of the Board of Trustees of the State Mining Bureau.

[Approved March 23, 1893.]

The people of the State of California, represented in the Senate and Assembly, do enact as follows:

SECTION 1. There shall be and there is hereby established in the State of California a Mining Bureau, the principal office of which shall be maintained in the City of San Francisco, which said Mining Bureau shall be under the supervision of a Board of Trustees, to be known as the Board of Trustees of the State Mining Bureau, and it shall be the duty of, and the Governor of the State of California is hereby authorized and empowered to appoint five residents and citizens of the State to be such trustees.

SEC. 2. The appointees shall take the same oath of office as other State officers, and when duly qualified and assembled shall constitute the Board of Trustees of the State Mining Bureau. They shall hold office for four years from the date of their appointment, or until the qualification of their successors, and shall receive no compensation for their services. They shall have control of all properties and funds of said bureau, and shall have the power by the name of said board to sue and defend. Three of them shall constitute a quorum for the transaction of business. They shall elect one of their number to be president of said board, and shall keep a record of their proceedings. They shall adopt rules and regulations for their government not in conflict with the laws of the State.

SEC. 3. It shall be the duty of the Governor of the State of California, and he is hereby empowered to appoint a citizen and resident of this State, having a practical and scientific knowledge of mining and mineralogy, to the office of State Mineralogist, which office is hereby created. Said State Mineralogist shall hold his office for the term of four years from the date of his appointment, or until the qualification of his successor. He shall take and subscribe the same oath of office as other State officers, and shall give bond for the faithful performance of his duties in the sum of twenty-five thousand dollars, said bond to be approved by the Governor of the State of California. He shall receive for his services a salary of two hundred and fifty dollars per month, to be paid in the same manner as the salaries of other State officers, and shall also receive his necessary traveling expenses when traveling on the business of his office, said expenses, when approved by the Board of Trustees of the Mining Bureau, to be allowed and audited by the State Board of Examiners. The said salary and expenses shall be paid out of the Mining Bureau Fund, herein provided for, and not otherwise.

SEC. 4. It shall be the duty of said State Mineralogist to make, facilitate, and encourage special studies of the mineral resources and mineral industries of the State. It shall be his duty: To collect statistics concerning the occurrence of the economically important minerals and the methods pursued in making their valuable constituents available for commercial use; to make a collection of typical geological and mineralogical specimens, especially those of economic or commercial importance, such collections constituting the museum of the State Mining Bureau; to provide a library of books, reports, drawings, bearing upon the mineral industries, the sciences of mineralogy and geology, and the arts of mining and metallurgy, such library constituting the Library of the State Mining Bureau; to make a collection of models, drawings and descriptions of the mechanical appliances used in mining and metallurgical processes; to preserve and so maintain such collections and library as to make them available for reference and examination, and open to public inspection at reasonable hours; to maintain, in effect, a bureau of information concerning the mineral industries of the State, to consist of such collections and library, and to arrange, classify, catalogue and index the data therein contained, in a manner to make the information available to those desiring it, and provide a custodian especially qualified to promote this purpose; to make a biennial report to the Board of Trustees of the Mining Bureau, setting forth the important results of his work, and to issue from time to time such bulletins as he may deem advisable concerning the statistics and technology of the mineral industries of this State.

SEC. 5. Said State Mineralogist shall have the right to appoint competent assistants and qualified specialists when necessary in the execution of his plans, and fix their compensations, but all such appointments and compensations shall be subject to the approval of and confirmation of said Board of Trustees, and shall not become effective unless so confirmed and approved. And it shall be the duty of the State Mineralogist to consult the Board of Trustees upon all matters pertaining to his official duties, and he shall at all times perform such duties subject to the supervision and approval of said Board of Trustees.

SEC. 6. It shall be the duty of the Board of Trustees of the State Mining Bureau, when the funds of the said Mining Bureau will permit, to procure and maintain the necessary rooms and furniture for the offices and uses of the said Board of Trustees and the State Mineralogist, and the museum and library of the Mining Bureau in San Francisco; *provided, however,* that the entire expenses of the State Mining Bureau for salaries, assistance, light, rent, fuel, furniture, and all other things pertaining to said Bureau must not, in any one year, be greater than can be paid out of the Mining Bureau Fund herein provided.

SEC. 7. The Board of Trustees of the State Mining Bureau shall manage and control all the finances of said

Mining Bureau, and shall make rules regulating the custody and disbursement of the funds of the State Mining Bureau, and the mode of drawing the same from the State Treasury.

SEC. 8. The Board of Trustees of the State Mining Bureau shall biennially report to the Governor of the State the condition of the Bureau, with a statement of the receipts and disbursements in detail, and with said report shall be incorporated the biennial report of the State Mineralogist, and the report of said Board of Trustees and State Mineralogist shall be printed as are the reports of the other State officers.

SEC. 9. The Board of Trustees of the State Mining Bureau are hereby empowered and authorized to receive, on behalf of the State, for the use and benefit of the State Mining Bureau, gifts, bequests, devises, and legacies of real or other property, and to use the same in accordance with the wishes of the donors; and if no instructions are given, by said donors, to manage, use, and dispose of the said gifts, bequests, and legacies for the best interests of the said Mining Bureau in the manner they may deem proper.

SEC. 10. The State Mineralogist may, with the approval of the Board of Trustees of the State Mining Bureau, prepare a special collection of ores and minerals of California, to be sent to any World's Fair or Exposition at which they may deem it advisable or desirable to display the mineral wealth of the State.

SEC. 11. The Mining Bureau Fund herein mentioned, and out of which all the expenses of the State Mining Bureau shall be paid, shall consist of such property or moneys as may come into the hands of the Board of Trustees of said Bureau by gift, bequest, devise, or legacy; of such moneys as may, from time to time, be appropriated by the Legislature of the State for the use of said Bureau, and of such moneys as shall be paid into the State Treasury for the use and benefit of said Bureau, as provided in the following section:

SEC. 12. It shall be the duty of the Tax Collectors in the several counties in the State and of the License Collector of the City and County of San Francisco, on the second Monday in January, April, July, and October, in each year, to transmit by express, to the State Treasury, all moneys collected by them from mining corporations, or from corporations formed for mining ores, or for supplying water for mining purposes under or by virtue of the Act entitled "An Act imposing a tax on the issue of certificates of stock corporations," approved April first, eighteen hundred and seventy-eight, and to forward to the State Controller, by mail, a certificate showing the amount of money so forwarded to the State Treasurer, and the date when the same was transmitted, and also showing the names of the several corporations from which the same was received, and the amount received from each. The State Treasurer shall receive the amounts so transmitted, and give duplicate receipts therefor, one of which shall be filed with the State Controller, and the other shall be forwarded to the Collector from whom the money was received; and after paying out of the money so received the charges for the transmission thereof, the amount of which shall be noted on the receipt filed with the State Controller, he shall retain the remainder in his hands and place it in the Mining Bureau Fund, said Mining Bureau Fund to be used only in the payment of drafts made for the expenses of the Mining Bureau established under this Act.

SEC. 13. Such Tax Collectors and License Collectors shall hereafter be required to pay into the County Treasuries of their respective counties only that portion of the moneys collected by them under the Act of the Legislature mentioned in the last preceding section, approved April first, eighteen hundred and seventy-eight, which is collected from corporations other than those mentioned in section twelve of this Act.

SEC. 14. The Board of Trustees, now known as the Board of Trustees of the State Mining Bureau, shall perform the duties of the Board of Trustees of the State Mining Bureau, as in this Act provided, and administer the affairs of the State Mining Bureau, as in this Act provided, until the appointment and qualification of their successors, as in this Act provided, and the State Mineralogist, now performing the duties of the office of State Mineralogist, shall perform the duties of the office of State Mineralogist, as in this Act provided, until the appointment and qualification of his successor, as in this Act provided.

SEC. 15. The Act entitled "An Act to provide for the establishment and maintenance of a Mining Bureau," approved April sixteenth, eighteen hundred and eighty, and the Act entitled "An Act supplementary to an Act entitled 'An Act for the establishment and maintenance of a Mining Bureau,' approved April sixteenth, eighteen hundred and eighty," approved March twenty-first, eighteen hundred and eighty-five, and all Acts and parts of Acts in conflict with the provisions of this Act are hereby repealed.

SEC. 16. This Act shall take effect and be in force from and after its passage.

The Garfield-Virginia Mines.

TO THE EDITOR:—These mines, owned and worked by the Consolidated Garfield-Virginia Mining and Development Co., have turned out to be very valuable property. They are located on the Tuolumne river, in Tuolumne county, and on one of the best mineral belts in California. Exceedingly rich rock has been found in these mines; the formation is black slate of metallic character; the ore is principally free milling. This company being in possession of valuable water-rights and a practically unlimited supply of water, the power for all purposes can be easily obtained. In a tunnel run in on the vein near the river and directly above the millsite, a large body of pay quartz was struck. This same tunnel will eventually give hacks of over 2000 feet. There are very few mines which have the same facilities and which can be as cheaply and easily worked as the Garfield-Virginia mines. Being worked entirely by levels from the mountain side, it saves the expense of hoisting

machinery, pumps, etc. Several mines on the same lead and within a short distance of the Garfield-Virginia, have been hoisted to prominent mining men recently.

A. C. M.

The Real Significance of the World's Fair.

The President, the members of the Cabinet, the foreign grandees and the military and naval officials went to Chicago, and on Monday of last week the great fair was formally opened. Here again it rained, and the fair grounds were half flooded and unequally muddy, but this did not prevent half a million people from being on hand. The clouds cleared away toward midday, and the ceremonies were held in the open air. There was a splendid assemblage of notables, including the Spanish Duke of Veragua, a lineal descendant of Columbus, who is the guest of the American government. Mr. Cleveland delivered the formal address, which was admirable, both in its matter and in its brevity. He said:

I am here to join my fellow-citizens in congratulations which best fit the occasion. Surrounded by the stupendous results of American enterprise and activity, and in view of the magnificent evidences of American skill and intelligence, we need not fear these congratulations will be exaggerated.

We stand to-day in the presence of the oldest nations in the world and point to the great achievements we here exhibit, asking no allowance on the score of youth. The enthusiasm with which we contemplate our work intensifies the warmth of greeting we extend to those who have come from foreign lands to illustrate with us the growth and progress of human endeavor in the direction of a higher civilization.

We, who believe popular education and the stimulation of the best impulses of our citizens lead the way to the realization of the proud national destiny which our faith promises, gladly welcome the opportunity here afforded to us to see the results accomplished by efforts which have been exerted longer than ours in the field of man's improvements, while in appreciative return we exhibit the unparalleled advancement and the wonderful accomplishment of a young nation, and present the triumphs of a vigorous, self-reliant and independent people.

We have built these splendid edifices, but we have also built a magnificent fabric of popular government, whose grand proportions are seen throughout the world. We have made, and here gathered together, objects of use and beauty, the products of American skill and invention. We have also made men who rule themselves. It is an exalted mission in which we and our guests from other lands are engaged as we co-operate in the inauguration of an enterprise devoted to human enlightenment; and in the undertaking we here enter upon we exemplify in the noblest sense the brotherhood of nations.

Let us hold fast to the meaning that underlies this ceremony, and let us not lose the impressiveness of this moment. As by a touch the machinery that gives life to this vast exposition is now set in motion, so at the same instant let our hopes and aspirations awaken forces which in all times to come shall influence the welfare, dignity and freedom of mankind.

We print this speech in full because it is worth everybody's reading. It emphasizes in the fewest words the real significance of the fair.

The President ceased speaking at ten minutes past noon. He paused a moment, then he grasped the electric button and pressed it firmly. Instantly the veil fell from the enormous golden statue of Liberty at the entrance of the lagoon, a hundred fountains spread their jets of water high in the air, a thousand banners were set free and fluttered in the wind, and 100,000 throats raised a mighty shout, whistles on the boats belched forth a shrill, ear-splitting scream, out on the lakes big guns thundered, haws were flung in the air, and afar the locomotives, taking up the sound, added to the fast-increasing volume of noise with the loud tooting of their whistles. Buffalo Bill's Indians and cowboys added their yells, and everything capable of producing noise within a square mile did its best in that direction.

A Dry Washer.

The *Genoa Courier* says: Last week Howard Beers gave an exhibition at Harris' store of the working of the Freeman "Dry Gold Separator," the most practical machine for working dry dirt we have ever seen. It weighs about 35 pounds and is conveniently arranged to be carried on a man's back, and only cost \$25. From two to four tons of dirt can be worked on it per day and it will save as fine colors as can be obtained with the miner's pan. The small machine is turned by a crank. The dirt is thrown upon a slanting screen on top, and falling through strikes upon a rifled table of wire and cloth. By means of a double bellows the air is forced through this fine wire screen in little gusts, moving the dirt up and down and as it passes down over the fine screen the gold lodges on the riffles. The machines are manufactured in Los Angeles and the large ones weigh about 250 pounds and are capable of working from 80 to 100 tons of dirt a day. They are said to be used with great success in Arizona. As soon as the weather settles, Mr. Beers will go to Pine Nut and make a test on Wm. Cohen's claim adjoining the Monarch. Old miners regard this as this best dry-wash machine ever invented.

Mining in Tuolumne County.

TO THE EDITOR:—One of the best though least developed mining counties in California to-day is Tuolumne. Within the last six months or so the eyes of mining men seem to have been cast in that direction. A number of mines have changed hands recently, while others in that county have been hoisted to prominent mining men. Capitalists seem to awaken to the fact that there are enough good mines to be found right at home, and that there is no necessity of going outside the United States boundaries, looking for mines which are principally on paper only or else almost inaccessible for purposes of working them.

M.

The Ideal Currency.

TO THE EDITOR:—"Once upon a time," a small State wanted a market-house. Instead of borrowing money on interest, the people, through their parliament, issued notes to the amount of \$20,000. These were paid to a contractor as the work went on, and with them he paid the wages of those whom he employed, who, in their turn, passed them to others in payment for food and other things, and so the notes were kept circulating and serving every purpose of money, which they were in fact. When the market-house was completed, it contained 80 stalls, and these were let to butchers at \$25 a year each. The notes were received by the State in payment of rent until all of them had been turned in—that is, during ten years—and from that time to the present the market-house has been a source of revenue. This is history, though not very widely known. For further particulars, see the *Star* newspaper of this city, April 8, 1893.

At first sight this looks like a very good scheme; on second thought the question presents itself, inasmuch as the market-house did not cost the State a cent, how did the State come to be the owner of it and derive revenue from it? On further reflection this question is answered as follows: The building was erected for the benefit of the community, and when completed it had a value beyond that of the material and labor employed in its construction. This extra value was created by the presence and activity of the community, hence was the property of the community, it was the "unearned increment." If anyone doubts this, let him consider what would have been the effect if the community had moved away from that vicinity; clearly the structure would then have lost almost all of its value. Hence, the State was justified in paying its notes by permitting the holders to enjoy the use of the structure, plus that of the unearned increment, during a limited period when, all debt having thus been paid, no owner other than the community could possibly exist. There is a profound lesson in this view, which I commend to the consideration of social reformers. My present concern, however, is with that aspect of the case which bears on the question of the currency.

Why may not this system be extended to the exclusion of every other? Let us consider.

Suppose two States, A and B, both moneyless, and both desiring to establish a medium of exchange. A puts a number of men at work digging holes in the mountain from which, with great toil and some danger to and sacrifice of life, they gradually win a quantity of gold. The Government converts that gold into coin, with a further expenditure of labor, and, after paying the wages of the miners, distributes the remainder of the money among the miners. This is simply free coinage of gold. The miners pay the coin to merchants for supplies, the merchants pass it to farmers, manufacturers, etc., and so in course of time the community finds itself with a circulating medium.

B, in the meantime, has put men at work digging a canal for the benefit of the community, and has given them its printed acknowledgment of service received, that is to say, notes. The laborers pay the notes to merchants for supplies, and the merchants pass them to farmers, manufacturers, etc., and so this community is also provided with money.

The two States are now in the following positions: A has a circulating medium and sundry useless holes in the ground; the substance of its money is worth its cost in the markets of the world. B has a circulating medium and a canal. The substance of its money is worth nothing, but the canal is worth more or less than its cost, according as it was judiciously planned and constructed, for it must not be forgotten that it is possible for the State to make a bad investment.

Coin and notes are alike certificates of service rendered by the holders. How much better than pieces of paper would the coins be if they could not be exchanged for service? and how much worse than coins are notes that can be so exchanged? Whether coin or note, the money, or certificate of service rendered to the State, is cancelled when paid to the State for service returned by the State to the individual, and may again be issued by the State to an individual for service rendered by him to the State. The ideal currency consists of printed promises, made by the State, to return the service of which they are the evidence. It has no other guarantee than the good faith of the Government and its ability to fulfill. A currency of good coin is also a promise, but it carries with it, in the substance of which it is made, the guarantee of the whole civilized world. Which is the best suited to our conditions?

The financier, statesman, or philosopher, who fails to take account of the human passions, prejudices, habits and faults is sure to err grievously in his plans, his legislation, or his deductions; and there are certain considerations which bear on the practicability of the ideal currency at the present day.

Governments are composed of men, and among men some are dishonest, many are unwise. The power of making money with a printing press has a great fascination for both of these classes. For the first, because they see in it an easy road to dishonest gains; for the second, perhaps, because they have a vague idea that a man may elevate himself by a process analogous to that of climbing up his own back. The first remember to forget, and the second forget to remember, that every dollar issued is a promise of service to be rendered at last by the State to the holder of the note.

To the unlimited issue of coin there is an insuperable obstacle in the limit to the supply of precious metal, but the only limit to the issue of paper is the law and the conscience; the law may be changed. Few men, still fewer aggregates of men, have been able to resist the seduction of unlimited credit.

If the only expenses of the Government should be for

the construction of railroads, telegraphs and other productive things, the danger of overissue would not be so great; but our Government has not even begun to occupy itself with industrial enterprises, except the postoffice which does not pay expenses. Its revenues are derived almost entirely from the various taxes, and, as the imposition of a tax is always distasteful to the people, it is much to be feared that if the country were given over to credit money entirely, the printing press would be put into operation whenever money should be wanted, and that money would be wanted too often.

If too much paper money is issued—and that has been the result of former experiments generally—the community finds at last that it owes more service than it can repay; that it is deeply in debt. To whom? To itself? What an absurdity! The community as a whole is indebted to the individuals who hold its notes. In business, men are nothing if not selfish; it is the instinct of self-preservation. As soon as a man who holds a considerable amount of the State's paper begins to doubt the State's solvency, he tries to exchange the paper for something else—horses or houses, corn or cattle—and prices begin to rise. It is really the value of the paper money that falls, and the movement once begun, it continues to fall with the acceleration of a body moving under a constant impulse. The expenses of the Government increase, while the revenue does not, and the printing press is set working again, and so on until the paper becomes valueless, or nearly so, and a general collapse of business results.

With a currency of precious metal, an excessive emission, if it were possible, would have the same effect; for a coin, as well as a note, is an evidence of debt because it is an evidence of credit, and credit cannot exist without debt. It shows that the holder has done some service which entitles him to a return. But, as the whole world wants precious metal, it is clear that the whole world must be sated with it before it can lose its value. The man who holds a piece of gold has a draft which will be honored in any but a savage country. This shows the essential difference between "credit money" and good coin. A paper currency fully backed by precious metal is in nearly the same position as coin, at least for domestic use.

If the single tax were established, and especially if the community should own the railroads, telegraphs, water works, light works, etc., the ideal currency should be safe and practicable. The State's rent-roll would furnish a sound basis for all the money that would be needed, to say nothing of the other properties. For the present I fear the ideal currency would be too dangerous to be adopted fully.

But the nation is in debt already to the extent of some six hundred millions in interest-bearing bonds. The debt would not be increased and the interest would be stopped if the bonds should be taken up and paid with legal tender notes. If the credit of the country is good enough to maintain the bonds, it must be good enough to make the notes current, hence the bond-holder who should surrender his bonds in exchange for notes would be as well off as if he should get gold for them, and the men who took advantage of their country's peril to try to saddle their fellows with a perpetual burden should be thankful if the people do not utterly repudiate the base transaction. In time of war we conscript *lives*, which can never be repaid. Why should we not also conscript money?

If we are under an obligation to pay the bonds in coin, why not buy coin with notes, then lift bonds with the coin, again buy the coin and lift more bonds, mature or not, until the whole accursed plot shall be defeated? As to bonds not matured, condemn them as we condemn a house or a field which lies in the way we wish to go? In so far as bonds are held by foreigners, of course the coin would have to leave the country unless the balance of trade should keep it here. But there is coin enough in the country to pay all the bonds, and, if not, we could buy bullion for notes and use that. It would be better that the debt should be owed to our own people, in the form of credit money drawing no interest, than to foreigners, who ask nothing better than that our people shall be their slaves, forever paying to them the product of their toil. Would such action lessen the nation's power to borrow on interest? A consummation devoutly to be wished.

We require to increase our currency by three or four millions every month, to keep pace with the population, therefore let us buy coin to that amount every month, and take up an equal amount in bonds. Does any one doubt that the people would sell coin for notes? Let that one explain why it is that the people decline the redemption of the greenback, of which over three hundred millions are in circulation. By the bye; that is another debt, and when the six hundred millions of bonds shall be converted into legal tender notes, there will be nearly a thousand millions of "credit money" afloat; yet we shall not from that cause owe a cent more than we do now, our debt will be made useful, and the interest will cease. Yet it will be a long step in the direction of the ideal currency. A war, either civil or foreign, would bring that mass of paper about our ears, perhaps, wherefore let us avoid war.

Fearfully and wonderfully made is the machine which grids the face of the people, and makes them the slaves of their masters, and an interest-bearing national debt is one of its most important levers of which the unsymmetrical fulcrum gives to the few the power to control the many. Is it not absurd that men should be permitted to issue money, to loan on interest, on the basis of bonds which also draw interest? This is a compounding of the lever which doubles its efficiency for squeezing the victims.

Oh, the masses, them asses! It does give me "that tired feeling" to see how meekly they stand before the tyrants who will mount them and ride, consuming the grain and pampering them with the chaff and straw within their ribs, the cudgel without. But what of it? Are we not a free people, the greatest nation on earth? and if we choose to put riders on our backs, spurs and all, shall we not do it? And are we not getting up in the world, since we are represented at the Court of St. James by an Ambassador in full bloom? Then let us make a joyful noise unto the Lord! Yea, verily, let us pray!

C. H. AARON.

The Double Standard.

TO THE EDITOR:—The arguments against the "double standard" used by Mr. Aaron in his discussion of the subject in your issue of April 15th can hardly be regarded as conclusive.

In the first place, let me premise that the object to be attained by any system is, or should be, under honest and intelligent legislation, to demonish the fluctuations in the exchange value of money—not to maintain a standard simply as such. That the bi-metallic system affords a better means of securing this result than does the single standard is obvious enough, even on Mr. Aaron's own showing. He contends that, on any change occurring in the relative value of two money metals, special contracts would be required to secure payment in the more valuable, thus showing that the natural consequence of the alteration in the relative value of the metals is to diminish the circulation of the more valuable and increase the use of the less valuable, which is a direct and efficient remedy for the anomalous state of things supposed (and only supposed), and must, in due course, restore the desired equilibrium.

It must be remembered that when once the ratio of the two metals is equitably adjusted, the only probable reason for any change in their relative market value would be diminished difficulty of production of one metal or increased difficulty in obtaining the other. With a mono-metallic system any change in the exchange value of money that occurs from the cause indicated is sudden and as permanent as its conditions, while with a bi-metallic basis both metals must be at the same time affected alike and to a far more intense degree—a coincidence in the highest degree improbable—in order to produce an equally disastrous result.

It will thus be seen that the bi-metallic monetary system is, to a very great extent, self-adjusting, and affords the most stable basis for payments in the future—that is, for contracts.

The argument of Mr. Aaron against two kinds of legal tender, on the strength of the depreciation of greenbacks, is irrelevant, as greenbacks are not money but promises to pay it, and depend for their exchange value on each man's idea as to what the promise is worth.

So much for the comparison of systems. Now, if a single standard be adopted, and that metal be, as it should be, desired which is subject to least fluctuation in its exchange value, the intrinsic superiority of silver to gold, in this regard, cannot reasonably be denied. Reasoning even *a priori* from the manner of production of each—silver invariably requiring expensive work and all the costly appliances of metallurgy, while gold is found to a very great extent ready made and is frequently obtained in large quantities with little expenditure of any kind—we would naturally infer that the exchange value of silver would be by far the more stable; but when, in addition, we review the monetary history of the past 20 years, when we find that, notwithstanding a ruinous demonetization policy and the resulting discredit and degradation of silver, it still maintains almost undisturbed its exchange value, as bullion, in relation to the more important commodities, wheat, cotton, etc., to the national loss, the ruin of multitudes of the producers of these commodities and the lasting disgrace of the authors of so disastrous a policy—in the face of this remarkable showing there is little excuse for the man who refuses to be convinced of the immeasurable superiority of silver to gold as a single standard of value.

Austin, Nev., May 6, 1893.

D. S.

Free Silver Coinage and National Banks.

TO THE EDITOR:—Much has been written for and against the coinage of silver. The time has come for the silver men to find out what class of men are opposing free coinage of silver, and, if possible, what their object is in so doing.

Most of the many magazines contain articles written from a gold standard view, but with such a national bank flavor that it can be seen they mean interest-bearing paper money, the gold standard taking second place. To get the Government to redeem national bank notes by any device is the main object. Almost every article written proposes some scheme to get government bonds to start banks. Some propose State, municipal and railroad bonds; others advocate no bonds at all—anything that will accomplish their object.

They all condemn the coinage of silver. This is Mr. Horace White's scheme from the "Annals of the American Academy," March, 1893: To continue national banks without bonds, he says, create a fund out of the present tax (one-half of one per cent) on bank notes; then add to this as further security the property the government officers secure when a national bank fails. He thinks this would be entirely safe for the Government to continue its responsibility to redeem the notes on these conditions. He says only five per cent of the banks fail; this would leave a very small amount of second-hand stuff.

Another by Mr. Moses Bruhl in the "Forum," March, 1893: It is head-lined "Cease Purchasing Silver and Issue Bonds." He proposes that the Government issue five hundred millions of bonds to bear two per cent interest, redeemable at the pleasure of the Government, and have no other kind of money above five dollars in value.

This would turn all United States Treasury notes and silver certificates that draw no interest into national bank notes that draw ten per cent per annum, in the usual double way these notes draw interest. This device does not look like a gold standard.

Yet another by the Hon. Henry Bacon in the "Annals," 1893, headed "Basis or Security for National Bank Notes," wishes to give State, county or municipal bonds as security. These bonds draw more interest than government bonds, and can be obtained in any quantity desired. If this was

adopted, the returns would be this: State bonds at 7 per cent interest, this going to the bank, and the same value loaned over the counter at 8 per cent. Fifteen cents per annum would be the cost to the people to circulate one dollar of national bank money one year.

This shows the object of the men who are crying about the dishonest silver dollar. Their plan to condemn silver is to begin at the formation of this Government and give a history of the values of silver and gold bullion, when a time is found that the gold bullion was a few cents higher than silver. We are told how very near we were to a financial panic, but it did not take place. A few years more silver raised above the gold bullion, and again the country narrowly escapes. Then a dose administered to remind us of the danger of keeping a double standard of money, and warned that the financial system of this country will go to pieces if it is not stopped. This is continued at short intervals up to about 1870. Here the record suddenly stops and skips a time when a villainous act was committed against silver in 1873, when it was demonetized. On this they are silent—very silent—but commenced about 1880 this way: "Now that silver has fallen in price below gold, lower than ever before, owing to overproduction, it became necessary for the United States to cease to use it for money and establish the gold standard." Cheap money, sound money will not circulate; the poor money will drive the good out of circulation.

Then we get a lesson of cheap money and inflations commencing with George Lau's operations in France and the Argentine Republic inflations in South America. All the miseries and troubles, both financial and physical, that afflicted these nations are carefully reviewed.

Then the Hohenzollern board of silver in Germany is worked, as also the fear that this would be made the dumping-ground for the silver of all nations.

The farmer is warned that, should silver be coined, his farm would not support him and his family; the laboring man that his wages will be paid in a debased currency (?). Why is all this done? Because the national banking system must be upheld by deception! The masses of the people do not understand this. The banks perform no services that cannot be done by the Treasury of the United States under the direction of Congress.

The banks absorb millions of dollars in interest produced by the labor of others, and give no value in return. Their parents were monopolies and trusts. They are worse usury gatherers than those thrown out of the temple at the beginning of the first century by the Savior of mankind for taking one interest on one value; but at the close of the nineteenth century these men come forward and demand two interests on one value, or they will give us no money. If the verdict of the people of this country is right, our Republic lives in fact; if wrong, it exists only in name.

Shasta, May 1, 1893. J. E. BELL.

Churntown District, Shasta County.

TO THE EDITOR:—The group of mines being opened up by Major Lyons has brought this district into prominence. A number of St. Louis capitalists are interested in the enterprise.

The Churntown district lies east and north of Old Diggings and is three-quarters of a mile due east of the Sacramento river, Sec. 22, T. 33, S. W. There are three parallel ledges on the location; the strike is 18 degrees east of north and the dip 42 degrees westerly. Tunnels have been driven on all three veins, in each instance opening up large bodies of ore. The west side of the hill is, however, the chief point of attack; 300 feet below the summit a tunnel is being driven with the object of tapping all three ledges. Owing to the contour of the hill this can be easily accomplished and a decided advantage will be gained by having the works on the side next the Sacramento river. This tunnel is now in for 300 feet; the survey gives 400 feet farther to the nearest ledge. Several hundred feet additional of backs can be obtained.

The formation is slate, metamorphic on the surface, but as depth is gained it becomes talcose, or more correctly, a hydro-mica slate. Iron staining gives the country rock a porphyritic character.

The grade of ore is high; there is a large percentage of sulphurets with free gold and telluride glance. Numerous assays have been made averaging several hundred dollars per ton. The quartz is of fine texture and similar to that in the Old Diggings district. The ledges average from two to four feet; the walls are well defined with slaty gouge, heavily mineralized; some limonite, rich in free gold, is found next the hanging wall. There are 500 tons of ore on the dumps. Croppings show strong for 3000 feet on the lode; so far as development work has been done no faults have been found; there is every indication that the ledges will reach a good depth. Timber and water are in abundance. Distance from Redding, ten miles. Elevation, 1600 feet. There have been very rich diggings in this district. The company is known as the Rich Gulch Miniog Company, Major Lyons, Manager; the other members reside in St. Louis.

Redding, Shasta County, May 6, 1893. WILLIAM G. HODSON.

IN the United States there are 32,000,000 men and 31,000,000 women. Men are in the majority in all the States and Territories except in the District of Columbia, Massachusetts, Rhode Island, North Carolina, Maryland, Connecticut, New Hampshire, New York, South Carolina, Virginia and New Jersey, in which there are more women than men. The District of Columbia has the largest proportionate excess of female population, and Montana contains the largest percentage of men. In New Jersey the two sexes are most nearly equally represented.

THE COBALT for plating is almost entirely used at present for coloring glass and pottery blue and for blue glaze. Its actual cost is said to be not more than that of nickel, but it is retailed at about five times this cost. If cobalt

plating, as suggested by Dr. Silvanus Thompson, were to come in, cobalt, being used more largely, would soon become as cheap as nickel. The chief ingredient of the most practical process is Epsom salts, through which the silvery metal is deposited. The polishing is done with scratch brushes, and the resultant white coating is almost indestructible by damp or smoky air.

New Estimation Method for Manganese.

Mr. Albert H. Low describes in *Iron* a new method discovered by him for estimating the manganese in ores. The length of time occupied by the entire analysis is said to be never greater than 20 minutes, and none of the usual constituents of ores interfere with the working of the process. The following solutions should be prepared: (1) A standardized solution of potassium permanganate, approximately 1-10th normal. (2) A solution of oxalic acid containing 11.46 grammes of $C_2H_2O_4 \cdot 2H_2O$ per litre; the exact strength of this solution is to be determined by titrating with the permanganate in the presence of hot dilute sulphuric acid in the usual way, and then its value calculated on the basis that $C_2H_2O_4 \cdot 2H_2O = Mn$; it will be found that 1 cubic centimeter will be equal to 0.005 gramme of Mn, or about 1 per cent when 0.5 gramme of ore is taken for analysis. (3) A saturated solution of bromine in cold water, an excess of bromine in the bottle; under the conditions to be described 25 cubic centimeters of this solution will precipitate about 35 per cent of manganese.

In carrying out the analysis 0.5 gramme of the ore is treated in a 16-oz. flask with whatever acids are necessary to decompose it. Usually 5 to 10 cubic centimeters of hydrochloric acid or aqua regia are sufficient. After all traces of free acid have been removed by heat, the solution is diluted with 75 cubic centimeters of hot water and an excess of zinc oxide added. The solution is boiled to effect complete neutralization of the acid. An excess of the bromine solution is then added; about 25 cubic centimeters is usually sufficient, and never more than 50 cubic centimeters should be added. The solution is boiled for a moment or two until the excess of bromine is expelled, and an excess of zinc oxide should all the time be observed in the bottom of the flask. When all the red fumes have disappeared the solution is filtered on a paper 5 inches in diameter and the flask precipitate washed several times with hot water. The precipitate and filter are replaced in the flask and about 50 cubic centimeters of dilute (1.9) sulphuric acid added. Into this mixture is run from a burette an excess of the oxalic-acid solution, and the mixture is heated to boiling; afterward more oxalic acid is added if necessary, so as to complete the solution of the precipitate. After diluting the solution with hot water, the excess of oxalic acid is titrated with the permanganate solution. The amount of oxalic acid actually consumed by the MnO_2 is thus arrived at and the percentage of manganese can then be calculated.

Professor Lorenz and Dr. Heusler, of Gottingen, contribute an interesting paper concerning the supposed volatility of the element manganese to a recent number of the *Zeitschrift für Anorganische Chemie*. Although the melting-point of the metal is known with tolerable certainty to about 1800° — 1900° , much higher than that of iron, no information has yet been acquired concerning its boiling-point. Professors Lockyer and Chandler Roberts, however, so long ago as 1875 pointed out that the metal was volatile at the temperature of the oxy-hydrogen blowpipe; and Mons. Jordan, in a communication to the *Comptes Rendus* in the year 1879, reported that in the manufacture of highly manganeseiferous spiegelisen near Marseilles, a deposit very rich in Manganese was usually found in the cooler portions of the furnace. Moreover, Mons. Jordan stated that during the casting of ferro-manganese red flames are produced, from which a heavy fume is deposited containing a large percentage of manganese. Mons. Jordan subsequently heated ferro-manganese to a white heat in a crucible in his laboratory, and ascertained that a diminution in the percentage of manganese actually occurred. These observations were considered somewhat surprising, inasmuch as the melting-point of manganese is so high, in the neighborhood of white heat, and it would appear that this volatility must be exhibited even at the melting-point itself.

Professor Lorenz and his colleague have therefore conducted a series of experiments with the view of ascertaining whether manganese is really volatile per se, or whether the volatility is due to the intermediate action of carbon-monoxide (derived from the carbon usually present) in forming a volatile but dissociable compound of a nature similar to nickel and iron carbonyl. It was first definitely proved that carbon-monoxide does not combine with manganese below the temperature of 350° , a fact which Mons. Guntz has recently independently pointed out. Experiments were then made at higher temperatures, using a new form of combustion furnace designed by Professor Lorenz, in which each individual burner is supplied with a blast capable of being regulated, the whole apparatus being equivalent to a row of blowpipes which will rapidly raise a thick porcelain tube up to a white heat. In the first series of these high-temperature experiments, coarsely-powdered manganese containing 7 per cent of carbon was heated to whiteness in a glazed porcelain tube in a current of carbon-dioxide, in order that nascent carbon-monoxide might be produced in contact with manganese by the reduction of the carbon-dioxide by the carbon present. After half an hour's heating the tube was allowed to cool in the stream of carbon-dioxide and then broken, when it was found that a large quantity of the manganese had volatilized and condensed again further along the tube, in the form of a thick black deposit somewhat resembling zinc dust.

Upon repeating the experiment with a current of carbon-monoxide, a similar result was obtained. Hence, manganese is certainly volatile in carbon-monoxide. But it was afterward found that equally good deposits of manganese dust were obtained when a current of either hydrogen or nitrogen, neither of which combine with manganese, was employed. It is, therefore, evident that manganese does not resemble iron and nickel in forming a volatile com-

pound with carbon-monoxide, but that the volatility is a property of the element itself, and is singularly manifested even at the temperature of the meltingpoint.

Vastness of the World's Fair.

The scope and immensity of the World's Fair are thus well set forth by Director-General Davis in his speech at the opening exercises:

"Fortunately, at the inception of this enterprise our Government was and still is at peace with the whole world. Commissioners were sent to Europe, Asia, Australia, British North America and the islands of the seas, so, to-day the whole world knows and is familiar with the significance of the great peace festival we are about to inaugurate upon this campus, and all nations join in celebrating the event which it commemorates.

"This inclosure, containing nearly 700 acres, is covered by more than 400 structures, from the small pavilion occupying an ordinary building site to the colossal structure of the Manufactures and Liberal Arts Building, covering over 30 acres, filled and crowded with a display of the achievements and products of the mind and hand of man, such as have never before been presented to mortal vision.

"Surrounding this grand plaza where we stand, and reaching from the north line to the extreme south, is the great mechanical, scientific, industrial and agricultural exhibition of the resources and products of the world. These have been secured from the four quarters of the globe and placed in systematic order under the supervision of these great departments, and while all material upon the grounds is not yet in place I am gratified to be able to present to the President of the United States at this time the official catalogue containing a description and the location of the exhibits of 40,000 participants in the Exposition. The number of exhibitors will exceed 60,000, when everything is in place.

"The citizens of our country are proud and always will be proud of the action of the Congress of the United States of America in authorizing and directing this celebration to take place; for the appropriation of more than \$5,000,000 in its aid, and for unswerving support and encouragement of the officers of the Government.

"To the states of the Union we are largely indebted for active and substantial support, to foreign nations which have representation upon these grounds never before witnessed at any exposition, as shown by the grand exhibits they have brought here, and the hundred of official representatives of foreign Governments, who are present on this occasion, we bow in grateful thanks. More than \$6,000,000 has been officially appropriated for these commissions in furtherance of their participation in the Exposition. The great nations of Europe and their dependencies are all represented upon these grounds. The Governments of Asia and Africa and the republics of the Western Hemisphere with but few exceptions are represented here.

To the citizens and the corporation of the city of Chicago, who furnished \$11,000,000 as a contribution, and in addition loaned the management the sum of \$5,000,000 more, are due grateful acknowledgements. To our own people, and the honored guests who share with us the advantages of this great international festival, and to the tens of thousands of exhibitors who contributed a larger amount than all the others combined, we are under the deepest obligations for their interest and co-operation.

The grand, concerted illustration of modern progress which is here presented for the encouragement of art, of science, industry and commerce, has necessitated an expenditure, including the outlay of our exhibitors, largely in excess of \$100,000,000."

Mail for the World's Fair.

Local postal authorities have received from Washington information concerning the delivery of mail at the World's Fair station, and for the benefit of visitors the same is published. The circular received is as follows:

"For the benefit of persons who intend to visit the forthcoming World's Columbian Exposition at Chicago, notice is hereby given to the public, through postmasters, that there is now in operation, in the Government building on the grounds of the Exposition, a branch of the Chicago postoffice, known as the World's Fair station, and which will continue during the entire period of the great Fair.

"This station postoffice will make regular collections and deliveries through its own force of letter-carriers from and to all parts of the Exposition grounds and will transact money-order and registry business, as well as all other business pertaining to a first-class postoffice.

"Visitors to the Exposition, not knowing before leaving home their precise location in Chicago, may find it convenient to have their letters and other mail matter addressed to the World's Fair station, or to have money orders payable there rather than at the main office at Chicago. Afterward, if desirable, they can have their addresses changed, either by notice to their correspondents, or by application to the postmaster at Chicago, or the superintendent of the World's Fair station.

"Mail matter intended for delivery on the Exposition grounds should be plainly addressed 'World's Fair Station, Chicago, Ill.,' giving, if possible, also, the precise locality in the grounds to which the matter is to be delivered, so that carrier delivery can be easily effected."

DIAMOND AND GRAPHITE, though chemically only different states of the element carbon, are almost completely opposite in their general character. The diamond is the hardest of all known minerals; graphite is one of the softest. The diamond is found in more or less symmetrical transparent crystals, generally colorless or faintly yellow, but sometimes with blue, grey, or other tints; graphite, on the other hand, rarely, if ever, occurs in well-defined crystals. Graphite is opaque, black in color, and has a metallic lustre quite different from that of the diamond; the latter, too, is a very bad conductor of electricity, whilst graphite is an excellent one.—Iron.

Work=Shop THE GREATEST
AND BEST
Companion

480 Pages
Solidly Bound
in Cloth

For Architects, Contractors, Engineers, Foremen, Railway men, Machinery makers, Jobbers, Salesmen, for Superintendents of Factories, Bookkeepers and Accountants.

The Compiler, having had many years experience in the mechanical arts, is enabled to judge correctly what is wanted for the class of people the book caters to.

An Inexhaustible Instructor for Shop, Office, and for Young Mechanics desirous of becoming perfect in their trade. Contains 498 Tables relating to metals, wood, and stone; 218 Rules to solve all mechanical difficulties. The Electrical Department, by a well-known Expert, is thorough and comprehensive. Price, \$2.50. Special terms will be given to live agents. Apply now. LAIRD & LEE, Chicago.

ARTIFICIAL LEGS AND ARMS
WITH RUBBER FEET AND HANDS.

It is not unusual to see an engineer with band on the throttle, or a conductor, brakeman, fireman, carpenter, mason, miner, in fact men of every vocation, wearing one or two artificial legs with rubber feet, Marks' Patents, and performing as much labor as men in possession of all their natural members.

Over 14,000 artificial limbs of Marks' Patents in use. Purchased by the U.S. and many foreign governments. One-half of the limbs furnished by us are made from measurements without our seeing the wearers. Fit guaranteed. A treatise of 430 pages, with 260 illustrations and a formula for measuring sent free. Address, A. A. MARKS, 701 Broadway, New York.

BUILDERS OF

"Sensible" Horse-Power Hoisting Whims.
(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, in hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breakage of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake wheels at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the bore in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stoppage and starting the horse.

It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, lever and sheaves, 1400 lbs.
Circulars giving Capacities and Prices furnished on application.

Mechanical Progress.

Cost of Operating Cable Roads.

At the meeting of the American Society of Civil Engineers, April 19th, a paper by D. Bontecou was read on "Notes on the Cost of Operating Cable Railways," an abstract of which appears in *Engineering News*. The writer stated that the information furnished by those who have built and operated such roads has not been in proportion to the importance of the subject, and that there has been much misinformation about the net results to be expected from a cable railway, inspired by commercial interests or by the tendency to generalize without sufficient study. He therefore presented certain facts and from them drew inferences as to some of the objections to the cable system. The cost of operation for a fast and frequent service is less with the cable than with any other form of traction; and the cost of first-class construction is so large that a suitable amount of business is needed to make a cable road profitable.

The amount of gross receipts necessary to justify the expenditure of a given amount in building a road is not well understood; and the paper presented the facts as to cost of operation of a single system in Kansas City, during the last fiscal year, as representing the inferior limit of justifiable cable operation, the net earnings having been about 3½ per cent on its cost, and the average number of passengers transported daily per mile of double track, 1706. There are 8.54 miles of double track disposed as a trunk line in the business part of the city, with three diverging feeders; and the system is operated as three distinct lines, with one common terminus; about two-thirds of the territory which is served is sparsely built up. There are three driving ropes, respectively, 14,200, 29,500 and 31,000 feet long. The powerhouse is at the junction of two of the lines, and a fourth rope, 9200 feet long, is driven from a separate house.

The speed of the cars is 7.8, 9.85 and 10.25 miles per hour. There are 716' of double-track curvature, with no grades exceeding ten per cent. The rope is 1½ inches in diameter and is carried on 12-inch pulleys in a conduit 36 inches deep. The combination cars each seat 40 persons, run on two four-wheel trucks, with 22-inch wheels, and have side-bearing grips. The plant at the main powerhouse consists of an electric-light plant, with one 36x58 inch and one 32x48-inch simple, non-condensing engine, which are run alternately by three 200-horse-power boilers. The driving drums are 12 and 14 feet diameter. In the branch powerhouse there are a 24x48-inch simple engine and two 175-horse-power boilers. The equipment comprises 99 combination cars, and the system has been in operation four years. The total cost of the plant is \$1,905,989, and, exclusive of the cost of franchise and grading new streets, the cost is \$223,184 per mile.

The total cost of operation, including injuries to persons and property, secret service, general miscellaneous expenses and taxes, and all other items of expense, was \$194,241.

Total car-mileage.....	2,830,732
Number of passengers carried.....	5,318,410
Number of passengers per car-mile.....	1.9
Average number of cars run daily.....	61

This shows a net cost of 6.9 cents per car-mile, or, if interest at five per cent be added, 11.02 cents. A larger amount of business would possibly increase the cost per car-mile one-half per cent. The fuel used is bituminous Kansas coal, with about 18 per cent ash. It consists of nut and slack coal mixed in the proportion of three to two, and costs \$2.01½ per ton of 2000 pounds. The writer estimated 2.1 pounds of coal used per ton-mile, and an average of about 575 horsepower as developed by the two engines.

The total indicated engine friction is 64 horse-power, and the total resistance of all the ropes when no cars are on the line is 200 horse-power, so that the actual traction of the 61 cars with their load, aside from the friction of the rope and engine, is about 4.01 horse-power per car. The net result of 99-100 cent per car-mile for all engine and fuel expense was given. Under more favorable conditions a better showing is made by a number of roads. One line in the East reports last year 2.28 pounds of coal used per car-mile, the average load being 4½ passengers.

The cost of ropes, with the expense of grip repairs, on the Kansas City road is 1.21 cents per car-mile. On the short main line a rope lasts six months, and on the independent branch line, for two years, the approximate life for the ropes being 20,000, 55,000, 68,000 and 130,000 miles. The cables are bought on a guarantee and the

cost charged out each month. These lines could be built to-day for less money than they cost five years ago. The cost of a main line in the East, built on a perfectly straight line for very heavy traffic, with a design to secure permanence and small operating expense, having 33,000 feet of rope driven by compound condensing engines of 300 horse-power each, was \$239,240 per mile.

In the census bulletin (*Eng. News*, May 23, and Oct. 24, 1891) the cost of ten cable roads was given at prices varying from \$160,000 to \$684,000 per mile, or an average of \$350,000 per mile. But such statistics are misleading; the more usual range of cost should be from \$150,000 to \$250,000 per mile, with a service not materially less than 1000 car-miles daily per mile of double track. These figures seem to indicate additional expenses per car-mile of from 2½ to 4½ cents. To reach conclusions as to the cost of a system it is proper to consider only such as have been built without entanglement with construction companies, or incompetent engineering, and have been run with a reasonable amount of skill and economy. In this, as in all other matters of construction, skillful designing has much to do with success. There has now been enough experience to take the consideration of cable roads as business propositions out of the region of conjecture, and enable the engineer to reasonably forecast their cost, the expense of their operation, and the probable returns.

Sawing Lumber in Mendocino County.

The Mendocino *Beacon* says in reference to the Navarro mill:

"The mill at this place is running full capacity. For the month of March, 1893, the mill cut 6031 logs in 21 days' run. But now with the new logs the output of lumber is greater, and W. H. Collyer, the foreman, says he expects the output of the mill for the present year to exceed that of 1892. Probably it would be news to those interested in the lumber industry to give the output of this mill. The mill on the north side is a Stearns' latest improved band mill, with Walter Huntly of Mendocino City at the lever. The output of this mill for the week just ended is 321,568 feet, or a daily average of 53,594 feet. The mill on the south side is a Climax mill, with Frank Menier of Tomahawk, Wisconsin, at the lever. The output of this mill for the week just ended is 334,780 feet, or a daily average of 55,796 feet; making a total output for the two mills of 656,348 feet per week, and a daily average of 109,390 feet. The total output for the year 1892 was 21,215,952,342 feet, on a run of 216½ days, making a daily average for the year, 101,051 feet. This mill has made some very remarkable records. In the month of October, 1892, from the 10th to the 15th inclusive, the Stearns' mill cut 435,470 feet, making a daily average for the week of 72,578 feet; and the largest cut for one day, running one side only, was made during this week, of 84,563 feet. This record was made by Patrick Connolly at the lever. The largest output for one day with both sides running was made July 14, 1892, consisting of 80,165 feet by the Climax mill, with Oliver Lafave of Cadalah, Wisconsin, at the lever; and 60,097 by Stearns' mill, with Patrick Connolly at the lever, making a total cut of 140,262 feet. The contract taken by the Pacific Equipment Company to equip this mill with the automatic sprinkler is nearing completion, under the supervision of M. W. Spencer."

GLASS BRICK.—In Switzerland there is now being manufactured a glass brick, or a brown building block, formed or molded flask shape with short neck at each end, 8 inches in length, 6 inches in width and 2½ inches in depth, with an air chamber through the center. The edges of the brick are covered, recessed, or ribbed and grooved to receive when laid a suitable cement of plastic material of such character that, after it has hardened, it will constitute a suitable frame or setting to keep the entire mass, roof or wall solidly together. The forms or molds, there being two different shapes, are pleasing to the eye, the lines or ridges being clean and smooth and of a sufficient thickness or strength to stand a pressure of 150 to 200 pounds to the square foot.

A HINT to intending traders with China comes from the United States Consul at Hong Kong, in the shape of advice to American manufacturers. The Consul says that it is absurd to seek to introduce such machinery as saw and planing mills, mowing and threshing machines and harvesters into a country where there are no large farms, and where human labor is so cheap as to be a drug in the market.

Scientific Progress.

Matter Held in Suspension in Moving Water.

In a late issue of *Le Genie Civil*, M. Gallois describes an easy experiment for demonstrating the action of solids held in suspension in moving water.

He says, take a bottle of white glass, about three inches in diameter and with a flat bottom; put into it to the depth of about 2-10 inch, some fine and very clean silicious sand, that will not interfere with the transparency of the water, with which the bottle is then filled. Cork it in such a manner as to exclude all air. Then give the bottle a rapid movement of rotation around its own axis, either by placing it on a turn-table, or by suspending it from a previously well-twisted cord.

It will then follow that all the sand will be projected upon the cylindrical sides of the bottle by centrifugal force. The rotation movement of the bottle will gradually communicate itself to the water, progressing from the sides to the axis, and as long as rotation lasts the sand will adhere to the cylinder. As soon as the water turns with the same velocity as the bottle containing it, suddenly stop the bottle. The sand will at once quit the sides and precipitate itself toward the center of the bottle in the form of a cloud, and it will then reassemble its particles on the bottom in the form of a cone, having the same axis as the bottle, and being higher as the velocity of rotation is greater. Finally the cone flattens as the velocity of rotation grows less, until the slope of the conical surface is the slope of equilibrium of grains of sand in still water.

The explanation of these phenomena is very simple. When the movement of rotation of the bottle is stopped, the water, by reason of its inertia, continues to turn; but the friction against the sides of the bottle tends to decrease the velocity of movement, and this decrease progresses successively from the sides to the center, in such manner that the relative velocity of the liquid threads is greater at the axis or center of the bottle. The sand is pushed toward the center by a force which is proportional to the velocity of the fluid. As this velocity decreases, the force of impulse toward the center decreases, and the cone flattens out, until it assumes the shape due to still water.

Copper from Birds.

It has long been known that six or seven per cent of copper could be obtained from turacin, a crimson pigment yielded by the feathers of the turacou, the African plantain-eating bird, of which there are 25 distinct species; but some new light has recently been thrown on the subject by Professor A. H. Church, of London. Of the 25 kinds of turacou, 18—namely, all those belonging to the three genera, turacus, gallirex, and musophaga—contain, according to this gentleman, the pigment turacin in from 8 to 18 of the primary and secondary feathers of each wing. It occurs also in the head feathers and crests of some of these birds. The pigment may be extracted by the most dilute alkaline liquids, producing a magnificent crimson solution, and it has a perfectly well-defined absorption spectrum. When a single red feather is burnt, the green flash of copper can, it is stated, be distinctly seen. Only one other animal pigment containing this metal is known; that is hæmocyannin, a respiratory pigment like the hæmoglobin of blood, not a mere decorative pigment like turacin. It contains, however, but a small proportion of copper. Professor Church also mentions turacoverdin, a green pigment occurring in the feathers of some turacous, and apparently also formed by the exposure to air and moisture of turacin, or by boiling that substance with caustic soda. When turacin is suddenly and strongly heated, it gives off a crimson vapor which condenses into a crystalline substance containing both copper and nitrogen, yet quite distinct in its properties from turacin. The average composition of turacin is: Carbon, 53.69 per cent; hydrogen, 4.60; copper, 7.01; nitrogen, 6.90; and oxygen, 27.74 per cent. The presence of copper in the substance is easily accounted for by the fact that bananas, the chief food of many of the turacou birds, contain this metal. The amount of copper in the turacin of a single bird is not quite one-fifth of a grain. Did the turacous yield metal of greater value than copper it is possible that their special breeding would have proved a more remunerative proceeding than investing in many gold mines. As it is, their capacity of yielding copper is merely regarded as a scientific curiosity.—Iron.

A SCIENTIFIC STUDY of dust has proved

that the atmosphere of New York improves with every story of ascent. The window sills on the ground floor of dwellings subjected to examination were found deeply covered with dust containing all sorts of unwholesome particles. The dust was less, and not so unwholesome, on the next floor, and this improvement was continued until only a thin layer of light and comparatively harmless particles was found.

EVOLUTION IN ARTIFICIAL STONE.—By a new process artificial stone is now manufactured free, it is claimed, from the usual liability to crack or fracture. The process is described as simple, that is, silicic acid, after being ground to powder, is cleansed from all impurities by ordinary means, and five to ten per cent of it mixed up in warm river or rain water, which is either applied to slaked or well-burnt lime, or is added to hydraulic lime; the resulting product of this process, which is silicate of lime, is mixed with sand and small portions of fluorspar. This mixture may be cast into molds, so as to give various shapes, as desired, and, on being removed, the castings are allowed to dry for from 12 to 24 hours, after which time they will be as dry as atmospheric air; they are then brought into a steam boiler and steam blown through, so as to drive out all air, after which the boiler is hermetically closed up and steam let in under a pressure of ten atmospheres. In this high-pressure steam bath the stones remain for 48 to 72 hours, afterward being submitted to a bath of boiling and saturated chloride of calcium during six to twelve hours, also under a pressure of about ten atmospheres, in the same boiler, and the condensed water may be used for the bath. These stones are allowed to dry in the open air, or, when desired to dry quickly, steam may be circulated inside the boiler after the chloride of calcium has been withdrawn and before the stones are taken out. Like ordinary stones, these are readily colored or polished.—Architectural and Building Monthly.

DIAMONDFEROUS NATIVE IRON, ETC.—Influenced by Mons. Moissan's recent discoveries, Herr Nordenskiöld, the eminent Scandinavian mineralogist, has contributed to the literature of the Paris Académie des Sciences some interesting particulars concerning a piece of meteoric iron, weighing 40 kilograms, or 88 pounds, which was found at Ovipak, in Greenland, and which he had vainly endeavored to saw or cut. This extraordinary hardness Herr Nordenskiöld, in view of Mons. Moissan's investigations, now attributes to the dissemination of black diamonds through the metallic mass. Herr Nordenskiöld further remarks that in the Swedish iron mines, particularly those near Norberg and Dannemora, large quantities of bitumen are met with which form two quite distinct varieties. One, for example, yields a considerable number of distillation products and burns leaving very little ash; the other, on the contrary, similar to anthracite, yields little on distillation, but yields much ash, in which is found, besides silicic acid, iron, lime, magnesia, etc., several per cent of the oxides of nickel, uranium (3 per cent), cerium, and gadolinium. These oxides, which have so far been only rarely observed, are also present, the celebrated mineralogist asserts, in the ash of a carbon which, in the form of large nodules, occurs in the oldest sedimentary strata, namely, in the alum schists, in Sweden, and in the grahamite of North America.—Iron.

A NEW GERMAN EXPLOSIVE.—The gun trials with the new explosive substance, which commenced at Jüterbogk on Jan. 31st, on which day Herr Krupp was present, have now concluded, writes a Berlin correspondent, and some details regarding the result of the experiments and the composition of the explosive which is to replace the powder at present in use in the German army are published here.

The new explosive is chiefly composed of a kind of fatty substance and is of a brownish color. It is of the consistency of frozen olive oil, and remains in that condition up to a temperature of 50° C. The substance, which is the invention of Dr. Weiss of the Gera Dynamite Factory, explodes neither by a blow, a shock nor a spark, but by the introduction of a fresh substance. The explosion is almost smokeless and produces very little detonation. The trials have given most successful results. There is practically no recoil, even when the gun is loaded with a heavy charge, and there is scarcely any heating of the weapon. The used cartridge cases can be filled again by a simple method. The new explosive can be employed for the existing artillery, but is not adaptable to the infantry rifle at present in use. Four new models of rifles have, however, been constructed and trials have been made with them.

Metallurgy and Ores.

SELBY

SMELTING and LEAD CO.,
418 Montgomery St., San Francisco

GOLD AND SILVER REFINERY
And Assay Office.

Highest Prices Paid for Gold, Silver and
Lead Ores and Sulphurets.

— MANUFACTURERS OF —

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scor-
ifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these sup-
plies since the first discovery of mines on the
Pacific Coast, we feel confident from our expe-
rience we can well suit the demand for these
goods, both as to quality and price.

Agents of the **Denver Fire Clay Co.** and
for the **Morgan Crucible Co.**, Battersea,
England. Also for **E. G. Denniston's** Silver
Plated Amalgam Plates. The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of silver guaranteed. Orders taken at the lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful **MacArthur-Forrest Process**,
Controlled by The Gold and Silver Extraction Mining
and Milling Co., H. A. W. TAYLOR, Pres.; LEONARD GOW,
V. Pres.; H. A. JONES, 2d V. Pres.; P. GOW, Gen'l. Manage-
ment; and Asst. Treas.; T. L. WISWALL, Gen'l. Mgr.
and Sec'y; PETER McCOURT, Treas.; W. L. COOPER, Eng.

TRADE MARK.

GLASGOW WORKS:
The Glasgow Gold Extraction Co.,
Limited, Scotland.
Also in Australia, South Africa,
New Zealand, Queensland, Etc.

General Office of Company:

Rooms 8, 9 & 10, Tabor Grand Opera House
Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill,
Denver, Colo.; The Livestock Gold Mining Co., Boulder,
Co., Colo.; The Puzzler Gold Mining and Milling Co.,
Boulder Co., Colo.; The Cripple Creek Gold Extraction
and Power Co., Colo.; Calumet Gold Mining Co., Middle
Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle
Creek, Shasta Co., Cal.; The Morcor Gold Mining Co.,
Fairfield, Utah; Champlin's Mines, Humboldt Dis-
trict, Yavapai County, Ariz.; The Crowned King and
Lant Chance Mine, Yavapai Co., Ariz.; The Union Mines,
Maricopa Co., Ariz.; The Revenue Con. Gold Mining Co.,
Revenue via Norris, Mont.; The Oreighton Mining &
Milling Co., Creighton, Cherokee Co., Georgia; and
others in course of erection.

The object of this company is to introduce the Mac
Arthur-Forrest process.

We have purchased from the Glasgow Gold Extraction
Co., of Glasgow, Scotland, the exclusive right for the
United States to use patents covering this process.

If you desire an experimental test communicate with
the secretary.

If the results of the tests are favorable, we will then
make arrangements to treat a quantity of not less than
five tons at Denver.

We are fully prepared to grant royalties to mine and
mine owners, or rights covering districts and counties.

The process consists of pulverizing the ore to a fine-
ness of about 60 mesh, and then subjecting the same to
an action of a very diluted solution of cyanide. A few
tubs especially constructed according to our diagrams,
for triturating, settling and filtering, is all that is re-
quired extra in connection with any kind of pulverizing
stamp or rolls.

The total cost, as a rule, does not exceed from \$2.50
to \$5.00 per ton.

The most desirable class of ore for this process
is so-called refractory gold ore, pyrites, hematite,
manganese and tellurium. We have also treated suc-
cessfully dry silver ore.

We will be pleased to answer any inquiries and fur-
nish any desired information. Address,

T. L. WISWALL,

P. O. Box 926. Gen. Mgr. and Secretary.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old
experienced, first-class Agency. We have able and trustworthy Associates and Agents in Wash-
ington and the capital cities of the principal nations of the world. In connection with our edi-
torial, scientific and Patent Law Library, and record of original cases in our office, we have
other advantages far beyond those which can be offered home inventors by other agencies. The
information accumulated through long and careful practices before the Office, and the frequent
examination of Patents already granted, for this purpose of determining the patentability of
inventions brought before us, enables us offer to give advice which will save inventors the
expense of applying for Patents upon inventions which are not new. Circulars of advice sent
free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Electricity.

Electric Buys for the World's Fair.

In the *Electrical Review* for March 12, 1892, was a very interesting illustrated description of the electrical buoys used to mark the "swash channel" at Sandy Hook. This was and is the only system of electric buoys in use in the world. Within the last few weeks a system of greater magnitude and electrical originality has been devised for use in Lake Michigan during the World's Fair, work upon which has already been commenced. This system, which is described in the *Review*, and which involves many novel features, will be one of the greatest electrical attractions at the fair. Foreign naval officers have been favorably impressed with the electrical buoys at Sandy Hook, and will probably be still more interested in the World's Fair buoys.

The peculiar situation of the World's Fair grounds with relation to the city of Chicago calls for unusual transportation facilities. In order to handle the immense crowds passing to and fro between the city and Jackson Park, and to ease up the load imposed upon the railroads, the World's Fair management decided to run a line of whaleback boats, which will carry passengers from opposite the Auditorium hotel to the World's Fair grounds. It then became necessary to mark a channel for these boats. It was at first thought that spar buoys would answer the purpose; but after it was decided to keep the World's Fair open at night, that plan had to be abandoned, and the only alternative left was to appeal to Commander J. J. Brice, U. S. N., in charge of the Ninth Lighthouse District, with headquarters in Chicago. Commander Brice communicated with the United States Lighthouse Board at Washington, requesting authority and permission to erect the required line of electric buoys similar to those at Sandy Hook. The Lighthouse Board communicated with Capt. W. S. Schley, U. S. N., inspector of the Third District U. S. Lighthouse Establishment, with headquarters at Tompkinsville, S. I. Finally Congress passed a bill appropriating \$20,000 for the installation of the World's Fair buoys. After a conference between Captain Schley and Mr. Ira W. Henry, the electrical engineer for the Bishop Gutta Percha Company, of New York, who installed the Sandy Hook plant, it was discovered that the problems involved at Chicago would preclude the use of the Sandy Hook system, the cost of the cable alone amounting to \$40,000. Mr. Henry immediately set to work and designed a new system, which is now being installed.

There will be 13 buoys located half a mile apart, extending from a wharf opposite the Auditorium hotel in the city of Chicago to the Casino wharf opposite the World's Fair grounds. The ends of this line of buoys are located about three-quarters of a mile off shore, but the middle of the line makes a wide sweep, extending two miles from shore to avoid the Hyde Park shoal. The submarine cable which will furnish the current is now being made by the Bishop Gutta Percha Company, and will be a stranded copper conductor No. 8, B. & S. G., insulated with gutta percha, with a jute bedding and armored with iron. It will be 14 miles long.

One of the chief points of novelty about this system is the fact that the buoys will be operated in series by an alternating current of 1460 volts. This cable, it is believed, is the longest submarine cable in the world carrying an alternating current of such pressure. The Columbian Exposition Company will furnish current at 2000 volts. A structure will be erected at the end of the Casino wharf in the form of a lighthouse. In this structure will be located a special converter now being made by the Westinghouse Electric and Manufacturing Company, of Pittsburgh, after designs by Mr. Henry. This converter will be used to transform the current from 2000 to 1460 volts, the pressure required on the buoy line. Besides this special converter, the lighthouse at the end of the wharf will be equipped with all necessary instruments to connect the submarine cable and the land line, together with a special Wurts non-arc lighting arrester.

The buoy is equipped with a 100-candle power incandescent lamp, and in the head of the buoy between the two horizontal iron bars of the cage will be sunk a special series converter. The connections of the cables are carried in slots sunk in the sides of the buoy and covered with strips of wood, screwed tight.

This line of buoys will mark a "fair way lane" from Chicago to the World's Fair grounds. Steamers will run up one side of the buoys and down the other. The average depth of water is 25 feet, as shown by

recent surveys made by Captain Schley and Mr. Henry from the lighthouse boat "Dahlia." The system will be in operation by June 1st.

Great credit must be awarded to Mr. Henry for the novel design of this system of buoys, which in all probability will become historic.

Storage Battery Cars on Second Avenue.

On Friday afternoon, April 21, says the N. Y. *Electrical Review*, the first public trial trip of the Second Avenue street railway storage battery cars was made and proved a success.

The car, equipped with the Waddell-Entz storage battery and motor, the body being manufactured by Brill Brothers, rounded the curve at 127th street, and started on its first trip with about 50 railroad celebrities aboard.

The batteries, 144 in number, occupy the spaces under both seats. The motor and gearing are remarkably noiseless, and the entire equipment of the car, viewed from the standpoint of a passenger, was satisfactory.

None of the storage battery cars which have been in operation heretofore has proved acceptable, the hum of the motor or the smell of the hydrogen being sufficient to condemn them in the eyes of the public, who in many cases preferred to them the present old-fashioned horse cars.

Messrs. Waddell and Entz and a corps of designers have worked together, and with their combined efforts have produced a storage battery and motor which seem to be a happy combination. The battery equipment of the cars weighs in the neighborhood of 4000 pounds, and its capacity is 350 ampere hours. In each separate cell are several pairs of plates, which weigh, together with the case and solution, about 30 pounds each. The fact that this battery is not composed of lead, and that it has not the objectionable sulphuric acid, or hydrogen fumes, recommends it as practical. The plates are iron and copper, and the solution is an alkaline salt of zinc; the voltage of the cell is about .8.

The company has a power-house at 127th street, which will soon be well equipped and prepared to furnish current for the 10 cars which will be used solely between 96th and 127 streets, to the exclusion of horses.

The motor of the car is remarkably well constructed and stands considerable hard usage. No brake is used to stop the car, but by an ingenious controller device the armature is short circuited, and the field coils are left excited. The large torque that the armature possesses enables the motor to start very quickly.

One feature of this motor is the gearing on the axle, cut with involute teeth, of a bronze made by the Waddell-Entz company, and it is a large factor that goes toward making it noiseless.

This trial trip of 31 blocks was accomplished in nine minutes, and the return to the power-house in like time. The directors of the road were perfectly satisfied with the trip, and it is possible that the entire line will be equipped with the storage battery cars, and the poor unfortunate car horse on the Second Avenue line will be relegated to perhaps some easier sphere of usefulness.

ELECTRO DEPOSITION OF COPPER.—A discovery which promises to be of great importance in the arts has recently been made in connection with the electro-deposition of copper and other metals. Heretofore these processes have been carried on by immersing the metal intended to receive the deposit in an aqueous solution of a salt of the metal to be deposited. The new process makes use of insoluble salts of the various metals, which are reduced to fine powder and mechanically mixed with water. The mixture is applied to the surface of the metal by means of a brush, to the handle of which is attached the electric conducting wire, so that the process of deposition resembles that of applying a coat of paint. Not only pure metals, but all sorts of alloys, are applied as coatings to other metals with the utmost facility by this process. The hull of an iron ship, for example, may be painted over with a tough, adherent and impervious coating of metallic copper, of any desired thickness. Experiments have been made which indicate that this process may be successfully applied to the plating of aluminum with silver or gold, a desideratum which has long been sought for, but hitherto apparently in vain. *Engineering News.*

There are three very noticeable features connected with the telephone service in England—it is controlled by the Government and under the direct charge of the postoffice department, its tolls are only about half what they are in America, and its wires are

all placed underground. That the Government looks out for its patrons as well as do the private companies in America for theirs is evident to any one who examines the service. For instance, long-distance wires are now being put down between London and Dublin, and Glasgow will soon be able to communicate with Belfast by the same means. When the lines are completed there will be a circuit taking in the cities of Dublin, Belfast, Glasgow and London.

Useful Information.

What Constitutes Millwork.

It is stated in the *Pacific Builder* that the items which make up a complete bid for mill work embraces the following: All doors, windows, transoms, sash and frames for same, thresholds, screen doors and sash, all ordinary inside and outside blinds and inside finish for doors and windows. All outside cornices, corner boards, water table, belt course, scroll work, all outside turnings, carved ornaments and verge boards when not fir. All veranda or porch post railing (when not square fir), balusters or cut work, filling below railing, arches and soffits, all molding and lattices. Wooden skylights and ceiling ash, including curbs for ceiling, ash and finish, when not fir. Inside base, angle beads, wainscot cap and paneled wainscoting put together and wainscoting, when not fir. Wooden sinks, drain boards, wash stand fronts, wooden wash tubs, capping for bath tubs, fronts for bath tubs with panels, wooden gratings for bath rooms and water closets. Material for closet shelving, drawers, hook strips, dressers and pantry finish. Posts for outside steps, including straight moulded railing and balusters and cut work under straight railing, also straight cap for buttresses of outside steps straight cedar coping. The contractor to furnish all dimensions and measurements. Alternation of repair work to be as per list of items agreed upon or furnished. All glass to be furnished (excepting metal skylight, sidewalk and store front plate, also art glass when price is not mentioned). Plain picture moulding only. The following items are not considered in a full mill bid: Rough furring or grounds for plaster work, rough arch ribs, rough brackets for iron cornices, easements for base and wainscot, capping for stairways. Ladders of any kind. Easements or crook portions of panel wainscoting. Covering for cornices, putting together of inside door frames. Twist turnouts or easements of any kind for wall coping. No patent sliding blinds or any other article which is patented. Or smoothing up of any inside finish, except which is put together at the mill.

UNLOADED BY AIR.—Advices from abroad describe a novel machine in use at Millwall docks, London, for the discharge of cargoes of grain in bulk, the principle applied being the removal of the grain by the creation of a strong current of air. The machine is erected on the barge, which is placed alongside the ship to be operated upon. To the machine is attached one end of each of six five-inch flexible pipes, the other end of each of which is carried into the hold or holds of the vessel and immersed a few inches in the grain. The engine is then started and the grain immediately flows at the rate of 100 tons an hour through the pipes into receivers, whence it falls by gravity into weighing machines, and then again by gravity into the craft sent by buyers to receive it. The machine in use has a power of 100 tons per hour, but the work done can be increased indefinitely by the addition of a corresponding engine power. The six pipes are worked together, but when necessary more or less of them can be shut off, and the rate of discharge is then reduced, but not in proportion to the number of pipes detached. With one pipe only in use the power exercised carries 38 tons an hour through it.

THE comparative efficiency of labor at high altitudes is discussed by Mr. E. Lane in the Nineteenth Century, in describing works on the summit tunnel of the Central railway of Peru, 15,645 feet above sea level. He says that up to 800 to 10,000 feet above the sea level the native laborers do about the same relative amount of work as at the sea level; at 12,000 feet the amount of work decreases, and at 14,000 to 16,000 feet a full third must be deducted from the amount the same man would perform at sea level. This applies to men brought up in the country. It takes about two weeks to accustom a man from the coast to do as efficient work at the higher altitudes, and his capacity gradually increases and reaches a maximum in a few weeks, or months, according to the constitution of the man. The majority of the

laborers are Cholos, or Indians, born in the Sierra. It takes them a long time to become accustomed to coast work. Mules and horses work well up to 17,000 feet, and in about the same proportion as the human beings mentioned. The perpetual snow line lies here at an elevation of about 18,000 feet above the sea.

LIGHTNING RODS ON SHIPS.—The methods adopted to protect ships from lightning are now so nearly perfect that it is only at long intervals that we hear of a vessel being harmed in any way from that cause. In the recently constructed men-of-war, great care has been observed in the placing of the lightning rods affixed to the masts. In some cases, branches have been run from the masts along the spars, each tipped with a solid platinum point. Several methods of sheathing are now being experimented with, and it seems that on those vessels containing a considerable amount of explosives, the rod will be run across the deck from the point where the mast enters, over the side and down to the sheathing. There can be little doubt that this will prove the safest plan yet devised. Human lives are far too precious to attempt any experimenting with, and the old motto, "In time of peace prepare for war," is especially applicable in the case of those vessels carrying magazines loaded to the decks with our modern explosives.—*Electric Review.*

TREATMENT OF LOW GRADE SILICIOUS ORES.—A correspondent writes: "The extensive additions to the reduction plants of the Broken Hill Silver Proprietary Company, of New South Wales, mark a very important epoch in the metallurgical treatment of the vast reserves of the low-grade silicious ores with which the mine abounds. To utilize the leaching plant, at present somewhat of a white elephant, Mr. Howell recommended, and the directors have approved, the erection of ten desulphurizing, chloridizing, revolving, cylinder furnaces. A lengthy series of experiments with the leaching plant has amply demonstrated the unsuitability of the lixiviation process to low grade silicious ores, owing to their diverse character and the high percentages of iodyrite and metallic silver. One of Mr. Howell's patent revolving furnaces was, therefore, erected near Brodribb's shaft about a year ago, since when 1200 tons of silicious material have been roasted and lixiviated, over 80 per cent from a 20-oz. gangue being extracted. The additional plant will be equal to an output of 300 tons of ore every 24 hours.

MAKING GLASS EYES.—In Thuringia there is a whole district which is dependent for its support on the manufacture of artificial eyes—husbands, wives and children all working together at this same means of livelihood. And yet, though these simple German village people turn out their produce by the dozen, no two eyes are ever the same. No artificial eye has its exact fellow either in color or in size in the whole world. The method of the manufacture is not a very complicated art. There are, firstly, glass plates, which are blown by gas jets, then molded by hand into the form of an oval-shaped cup. Then there is the coloring of the eyes, which is effected by means of tracing with fine needles, the tints being left to the taste of the individual worker, though the scope of their taste is necessarily limited to grays and blues and browns and blacks, which colors are assorted together before being eventually dispatched to their various destinations.

In building an earth dam 85 feet high and over 1000 feet long for the water works at Santa Fe, N. M., the upper half of the dam is puddled in layers, a herd of 115 goats having been bought expressly for puddling. These goats are in charge of a herder, who keeps them in motion when on the dam, which is stated to be from 12 M. to 1 P. M., and from 5 to 6 P. M. each day.

CONTRARY to what most persons would infer, it is said on the authority of the United States Department of Agriculture, after careful tests, that tapping the pine trees of the South for turpentine is not injurious to the timber, and that the lumber is in no way affected by it. The turpentine industry, with a product worth \$10,000,000 annually to the South, is thus a clear gain.

To the World's Fair!

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.
H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ZELE.—Amador Ledger, May 5: At the Zele the work of repairing is still going on. B. F. Taylor has had for the past week a force of men at work laying the new pipe which is to convey water from the reservoir to the mill. J. H. Tibbits, the popular and successful superintendent of the Albany Gold Mining Co., has, in addition to his other duties, assumed the position at the Amador gold mine made vacant by the resignation of J. P. Darling. Fisher and Shay, who for some time have been trying to strike the old Griselbach ledge, upon Wednesday were rewarded by finding the long-coveted lead. It proved to be about three feet wide and immensely rich, going up into the hundreds of dollars per ton.

PLYMOUTH.—Cor. Amador Ledger, May 5: Mr. Jones, the superintendent of the Bay State mine, has just returned from San Francisco, whither he has been to purchase machinery for a new hoisting works for the Bay State mine. He informs me that he bought a new 60 horse power engine and boilers, all complete, and that they were shipped last Saturday. They will be placed upon the ground in a few days, and in a short time operations on this celebrated mine will be resumed in first-class style, and in the near future the reports from this mine will compare with the other great bonanza mines of Amador county. I saw Mr. Wild, of the Wild & Wheeler mine, this morning, and he states that their five-stamp mill is still running night and day on fair-grade ore. He says the company is more than pleased with the results. A. B. Sammers, managing agent for Dr. Boyson, is pushing the work of developing the old Pioneer mine, south of the New London, with very encouraging results. V. Smith, superintendent of the Osceola, is pushing the work of development as fast as possible. He states that he thinks he will strike the ledge in a short time, and that the Osceola Company of San Francisco will be very agreeably surprised to find themselves the owner of a bonanza as rich as the now celebrated Baldwin mine, just across the river, which Mr. Smith claims is on the same chute of ore. All along the line of the mother lode from Plymouth to the Cosumnes river assessment work and prospecting is being carried on with unabated zeal, and in the near future we predict some rich development of this district.

Humboldt.

SOMMES BAR.—Blue Lake Advocate, May 6: Mr. A. Brizard and son Brousse, of Arcata, who left two weeks ago for a trip to the mountains, got back to Blue Lake the middle of this week. They made the grand rounds, going as high up as Sommes Bar. The placer mines were all in operation, with no end of water. Henry Theerman also says that this has been an unusually prosperous season for mining men. All the mines about Sommes Bar are running and apparently doing well.

Inyo.

FROM BIG PINE.—Inyo Register, May 4: The hauling of borax from Saline valley is now going on in good shape. Three teams are now constantly reducing the surplus which accumulated at the works during the unpleasant weather of February and March. Dan. Hall just broke the record on time, and John Counts knocked out the record for quantity, he having pulled in 20,400 pounds with a mixed team of small-eared mules and straight horses, numbering ten in all. H. W. Barton is in from his extensive field and shows some specimens of borax made in small cans, which is pronounced to be excellent. The impression is growing that Saline valley will soon be noted for the quantity as it now is for the quality of its borax output. I. H. Coe and Andy Fife will commence the leaching of Montezuma ore some time this week. Mr. Coe has confidence in the Montezuma property, and if their process of reduction operates successfully, excellent works will be erected at the mine in due time. S. P. Roberts of Big Pine will resume work at his Pine Mountain claims as soon as the snow will permit, and hopes to enlist capital sufficient to make that a good permanent camp. S. G. Gregg and Dick Whitaker have their sluice-boxes set at their placer claim southwest of the hamlet.

Placer.

DIVIDENDS.—Placer Herald, April 29: The old Breece & Wheeler still pays big dividends. The Hidden Treasure pays as rich as ever. Quite a large force is at work. There is a prospect of the Hogsback starting up this spring. At the Black Canyon the tunnel has been completed and gravel struck. The Red Point is not paying much at present. The Pioneer mine is paying big. Work will be resumed on the old Weske mine this spring. On Wednesday of last week the owners of the Ben Franklin mine at Yankee Jims cleaned up \$2300, the result of 150 days' work for one man. The gold is of very fine quality, being worth \$18 per ounce. Work at the Gray Eagle began on the 17th. The company intend to run a new tunnel, which will be about 4800 feet long. The pay will open up the mine at a lower level. The pay streak at the Dardanelles is irregular, as the cement shuts it off at intervals. In places the cement runs to the bedrock; wherever it lifts the pay is big. The boring machine for prospecting gravel channels is at work on the divide. The Drummond mine has temporarily shut down.

Mono.

THE BONIE STRIKE.—Bodie Miner, May 5: The Bodie stock has been quite lively during

the past week, jumping up from 25 to 75 cents and back again yesterday to 30 cents. It was reported on the streets that an important strike had been made in the upper levels. Our reporter interviewed Supt. Kelly on the subject, but all the information he got was, "it is looking well in the face." It is the general opinion here that a small vein of very rich ore has been discovered, but what it will amount to, time alone will tell.

THE STANDARD MINE will close down to-day and the mill will follow Sunday for want of wood. We understand that it will be about three weeks before operations will be resumed. In the meantime the shaft will be retimbered for 100 feet or more, and some necessary repairs will be done to the machinery at the mill and mine.

OPERATIONS have been resumed at the Summit mine. At present the force employed is small and the work done is on a limited scale.

Nevada.

THE CHARONNAT MINE.—Transcript, May 5: Colorado parties are negotiating for the purchase of the Charonnat quartz mine at Canada Hill. The property is owned by Geo. C. Gaylord. Several years ago this mine was considered one of the best in the district and employed a large force of men. It was not worked to any great depth, and the opinion of miners is that if the shaft was sunk down 100 or 200 feet deeper good rock would again be found. An expert was here from Colorado last week and made an examination of the mine. The company represents are anxious to get hold of mining property here. They mean business, and Mr. Gaylord thinks the sale will be consummated before long.

MINING AT HUNT'S HILL.—Transcript, May 6: Some very good paying gravel is being taken out at the Ah Sing Mining Co.'s mine, which lies adjacent to A. G. Turner's claim, known as the Eastern and Maine mine. There are some 16 coolies who own this mine, and during the last five years a great deal of gold has been extracted and but a very small part of it circulated this side of the Celestial soil. After a three months' run their long toms yielded the sum of about \$5000, which was far above all expenses. The mine was purchased about 12 years ago for \$3500 by this Chinese company, and since then many thousand dollars have been unearthed. The mine adjoining, owned by A. G. Turner, is located on the same lead, and the prospects at present bid fair to succeed. The gravel is very hard at present and requires to be crushed. The gravel extracted by the Chinese requires no crushing and is simply shoveled into boxes. Mr. Turner is in hopes of soon finding this same quality of gravel in his own mine, and if he does there can be no doubt as to its worth. The mill that he has erected affords him a good opportunity to prospect the dirt as it is taken out. At present the bedrock is pitching off rapidly, but the drifts are being run on a level grade with the hopes of soon finding the rock rising again. Most all the good paying ground in this locality has been on high bedrock. There is gold in all the dirt, which is an encouragement to press on.

THE DIAMOND MINE.—Grass Valley Telegraph, May 4: Mr. Thomas, the superintendent and principal owner of the Diamond mine, informs us that the work of pumping and sinking upon the property has been commenced. This is a comparatively new venture and is in a splendid district. The company will develop the prospect to its fullest extent.

CONTRACT AWARDED.—Transcript, May 2: The contract for erecting a hoisting and pumping plant on the Reward mine has been awarded to Martin Bros. & Muir, proprietors of the Miners' Foundry. The contract calls for the erection of the necessary building and all machinery, and the same to be first-class in all respects. The works will be put up as soon as possible. The owners of the Reward mean business and intend to open their property in a systematic manner.

TO BUILD A MILL.—Grass Valley Union, May 2: Last evening the Baltic Mining Company, of this city, held a meeting at the office of the company and let contracts to make machinery and erect a five-stamp mill at the mine. J. M. Lakenan, Grass Valley's foundryman, being the lowest bidder, was awarded the contract to furnish the machinery, wheels, pipe and everything complete, while Mr. Joseph Everett, the millwright, was given the contract to erect the mill, lay the pipe and get everything in working order and ready to start up. Mr. Schneider, superintendent of the mine, informed a reporter that it is expected that the mill will be on the ground and ready to commence crushing within six weeks from the present date. The contract to furnish the lumber has not been let yet, but it is most probable that it will be awarded to C. W. Kitts, of this city. Mr. Schneider feels very much elated over the future prospects of the Baltic. He says that it is looking better every day.

Plumas.

A GOON VAIN.—Plumas National, April 29: Sam W. Cheyney, superintendent of the Jamison mine, arrived in Quincy on last evening's stage. From him we learn that in making a crosscut to the southwest, from the lower tunnel in the Jamison mine, a small vein of very good ore was passed through. It is about one foot wide. The snow in the vicinity of the mine is yet quite deep and it will delay repairing the injury done by the floods early in the winter until the latter part of May. Mr. Cheyney will soon revisit Shasta county, where his company owns the Mammoth quartz mine, recently purchased by it and for which it is now securing patents.

AT SHORAS HILL.—At Shoras Hill, Henry Orr and Frank Terry are at work prospecting the Incubus gravel mine, owned by Orr, Edwards & Stephan. They are trying to find the channel supposed to have been the feeder of

the Elizabethtown and Newtown channels. Last season they put down a shaft 40 feet and found gravel 20 feet from bedrock. Recently they started a shaft 600 feet north of the other. Yesterday, very fine looking quartz gravel was reached. The company will sink another shaft between the two mentioned, with the view of thus reaching the center of the channel. The company owns 117 acres of ground, and the indications are that it will have a good mine.

WORKS COMPLETED.—The hoisting and pumping works at the Mill Shaft, about two miles above town, on the Golden Wreath placer claim, have been completed, and the work of getting the water out of the shaft is now in progress. The hoisting works are of a very substantial character in their entirety. A 10-inch pump is to be run by steam. M. S. Light has been doing most of the machine work and R. W. Young the carpentering. It is considered one of the strongest pieces of work of that kind ever erected in the county.

STRIKE IN THE HALLSTED MINE.—National Bulletin, May 6: Chas. R. Thompson came down from Spanish Ranch Monday, and brought with him a specimen of ore developed last week in the Hallsted mine on the East Branch. This piece of ore is very rich. Of course it is only a hand specimen, not shown as a sample of the great body of the vein which, on the surface, was 45 feet wide. However, it is a part of a discovery believed to be very rich, especially when the quality of ore in the recent development is viewed in connection with the vast extent of the quartz lode of which it is a part. A few years ago, a milling test (a four-stamp mill being used) of the surface ore was made, and the returns proved that it would pay. Since the time when this test was made, the Hallsted Bros. have been running a tunnel to tap this chimney 150 feet from the surface. They reached the ledge last week, and found this body of excellent ore. They will continue the tunnel to ascertain the probable length of this chimney. In due time a crosscut will be made. This immense lode has been cut by the East Branch of Feather river, and the bed of this stream is about 2000 feet lower than the present development. At the foot of the hill the vein is exposed. By running a tunnel of about 2000 feet the present chimney could be reached at a depth of 2000 feet. This great quartz lode is traceable across the mountain from East Branch to the North Fork of Feather river, a distance of over four miles. Hence it is a body of ore practically inexhaustible, and it is so located that capital could operate it very cheaply, the East Branch being the source of an unlimited amount of water or electric power for milling and mining purposes, while plenty of timber is at hand. It is the opinion of many old practical miners that the Hallsted property is one of the great future mining propositions in Plumas county. It is one of those mines that a poor man cannot equip and operate. It needs capital in the hands of practical mining men. It is a big proposition of merit, promising rich returns to a company of means to properly develop and equip it.

LA PORTE.—Cor. Plumas National Bulletin, May 6: From Supervisor McIntosh, who reached Quincy Sunday evening, we learn that the snow is yet about five feet deep at La Porte. This fact, however, does not deter the people of that pioneer mining town from making preparations to celebrate the Fourth of July. Considerable drift mining is in progress in that section. Thistle Shaft is now employing about 80 men and work is progressing very favorably. It is generally understood that the mine is paying quite satisfactorily. Undoubtedly it is a good mine and is one of the biggest gravel propositions in this part of the State. It is understood that the Claybank mine, near La Porte, has let a contract to run 1000 feet of tunnel. It is reported that Messrs. Hendell, Neff, et al., are taking good pay from the Excelsior, \$7 to the car being reported. The Suffolk is also doing well. Gould & Spencer, of Gibsonville, are doing some mining, with good prospects of success. Frank Cayot, of La Porte, is doing some work on his mine at Cascade.

Shasta.

A GOON PROPOSITION.—Redding Free Press, May 6: L. E. Rice, of Tacoma, writes to Dr. Hodson that his company is prepared to put up a plant in Shasta county, of 200 tons capacity, that will not cost any miner a cent. Mr. Rice proposes to have an interest given his company in the mines from which the ore may be supplied to the works. The process is a rapid and cheap one, and as no miner is asked to put up any money toward erecting the plant or the working of the ore, it is worthy of every consideration. Mr. Rice claims that he can work Shasta county ores up to 93 per cent, at a cost of \$2.50 per ton. Dr. Hodson has already sent him many samples from our mines. A proposal is made by Mr. Rice that a carload of ore be sent by the miners of Shasta county to his works in Tacoma, Washington, in order that they may be convinced that his process will do all that he claims. The smelting is done by electricity, and many authorities are of the opinion that this is the coming process that will solve the problem.

A LOT of mining machinery arrived this week for the Quartz Hill mine, formerly owned by Rube Clark, but now controlled by Benton Jones, of this city. Bent will have ten stamps running shortly on ore that is said to be very rich. He claims that with the appliances at hand he will be able to save nearly all the gold. Mr. Jones secures control of this mine on a bond, agreeing to pay \$20,000 for it at the end of three years, or sacrifice all improvements.

THE Gladstone mine, at French Gulch, cleaned up a \$17,000 brick as a result of the April run. The mine looks fine. Dr. C. H. Cummings, who owns the Morning Star mine, in Oregon gulch, was in town this week and reports making good clean-ups lately. W. P.

Miller, the mining man, will soon commence the erection of a plant at Middle creek, in which his new patent for saving and solidifying the slums will be used.

FROM SOUTH FORK.—Democrat, May 5: The South Fork reduction works are working ore from the Lewis mine. E. L. Bellon's mill is said to work fine. Mr. Ballon has a new concentrator, the first that has ever been sent out. R. Thistlethwaite, manager of the Crystal mine is expected back in a few days to commence work on the mine. Dunham, Martin & Co. will begin work on the Rustler in a short time. W. D. Ball is getting some fine ore out of his mine.

Sierra.

MINE SOLD.—Mt. Messenger, May 6: M. Lawler and Dan Glavin were here from American Hill this week in connection with the sale of the Mount Morlo quartz ledge below the old Pilgrim mine at that place, owned by a local company, that brought, we understand, about \$30,000. It is undoubtedly good property but lack of finances prevented the old owners from developing it. A San Francisco company is the purchaser.

THE Wide Awake Mining Company of this place has levied an assessment of five cents per share, delinquent June 6th.

TOM BASSLAR, Sam Tym and Albert Butler have leased the upper end of J. D. Newhouse's placer claim at Mobile Flat, and will immediately begin work.

Siskiyou.

ON SALMON RIVER.—Blue Lake Advocate, May 6: There have been a number of arrivals this week from the placer mines on the Klamath and Selmon, all of whom aver that the miners have all the water they want and more, and are as busy as bees. It would not be easy to enumerate the different placer mines in what is known as the Salmon river country. They are strung all along the river and the fact that the owners thereof are at work on them is pretty good evidence that they pay. Charles Leveque, a former citizen of this section but now a resident of Siskiyou, reached Blue Lake Wednesday afternoon. Mr. Leveque has been prospecting in the Salmon river country, having spent the winter, which he assures us was an almighty rough one, entirely alone. At the Fordyce mine, at the forks of Salmon, where Will McLeod, Dan McDonald, Angus McPhee and Lem Fordyce are, a lead has been struck and the prospect is encouraging. The Hennessy mine, some 20 miles from there, is in operation and, Mr. Leveque learned, is paying very well. Work in the New River mines, Trinity county, he was informed, is going forward, the Ridgeway alone excepted. The Salmon river country is full of prospectors, Mr. Leveque says, and some of them have found good locations. He himself has an excellent mine to which he expects to return after a brief vacation in this section.

Trinity.

GOON PROSPECTS.—Shasta Democrat, May 5: We had the pleasure, last Thursday of meeting Mr. Fordyce Bates of Minersville, Trinity county, who spent the day in town. He anticipates lively times in Trinity this summer, in both quartz and gravel. He believes the best gravel mines in Trinity are yet to be discovered and developed, in the cement gravel in prehistoric river channels that are now known to traverse throughout that county from northeast to southwest. A lead of that gravel was recently discovered in that county that has paid \$25 a day to the man drifting.

Tuolumne.

POCKETS.—Tuolumne Independent, May 6: Thos. Birney and Joel Hudson had the good fortune to strike a rich pocket in their mine on Bald mountain. We have heard the sum estimated as high as \$3000. We hope it is much larger. Tom says if it continues to pan out he hopes to be able to adjourn from hard work, build a nice home in Sonora, settle down and stay here. Jacksonville is coming to the front. Last week A. S. Orcutt struck a nice pocket in his mine at that place. At 100 feet from the surface, where the vein is about two inches wide, a pocket was found large enough to hold about \$500.

A MINING REVIVAL.—Sonora Democrat, May 6: It is now almost certain that the mining industry here is to be revived to an extent that will be fairly surprising, especially when the dull times of the past few years are considered. The Gem mine, near Jamestown on Whiskey Hill, being worked by the Henslee boys, is furnishing ore of high grade. We are informed that a 14-days' run yielded \$900. The Lady Washington, Richard, and New Albany mines will shortly pass into the hands of the San Francisco capitalists who have been negotiating for the purchase of them. A few minor details in perfecting title have prevented absolute purchase sooner, but now the sale is about consummated, and things are looking very hopeful for active operations on these mines in the near future. Mr. Wm. Johns, formerly superintendent of the Soudsby mine and also of the Eureka mine at Summerville, has bonded the big vein at Cherokee belonging to the Smith brothers. He has engaged to sink a shaft 200 feet deep on the vein and hoisting gear is now being erected at the Sonora Foundry for the purpose. This vein is claimed to be an extension (to the north) of the Eureka and Dead Horse mines. Tests of the ore show that the mine will pay well with the water power available. A pocket mine situated in the gold-bearing district of Brown's Flat, and being worked by T. C. Birney, Henry Munroe and George Wainwright, has been doing the grand in remunerating its hard-working owners this week. Mr. Munroe exhibited a piece of quartz in town Monday that fired glittered with gold, containing nearly \$400. By Tuesday evening \$2500 had been taken out and Wednesday morning the gentlemen resumed the easiest work ever done in a

mine—extracting gold. It is thought that the "pocket" will yield about \$4000. Work on the Belcher Consolidated mine, near Groveland, is being steadily prosecuted under the management of Frank Hill. The steam hoisting works will soon be in operation. The ore shows well in free gold and is of good paying quality. Mr. Hill has ordered one of the Blanding amalgamators. These amalgamators have been proved in practice to save the gold very closely, and the principal on which they operate is now in use in Nevada county and also in the extensive mines of Johannesburg in South Africa. They are manufactured by the Sonora Foundry. The Belcher Con. mine was sold in London on the report of Mr. Louis Blanding and a mill erected on the mine by him. The mill contains one of the Blanding crushers.

NEVADA.

Washoe District.

CON. CAL. & VA. MINA.—*Virginia Chronicle*, May 6: 1500 level—Have continued to extract ore and old fillings in working upward in the old south stope, from the 10th to the 16th floors, above the sill floor of this level. 1650 level—Have continued making necessary repairs to the drifts on the sill floor of this level. We continue to extract some ore from the old stope, eight floors up in the nraise, No. 6 carried up from the main northwest drift; also from the old stope in working north from the crosscut run west from the northwest drift. Have continued to stope out ore of fair quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. Have extracted during the week from all parts of the mine 567 cars of ore about 560 tons. Shipped to Morgan mill 662 610-2000 tons of ore. Average assay value, per railroad car samples, \$27.11. The assay value per battery sample of all the ore worked at that mill during the week (665 tons), was \$23.36 per ton. Shipped bullion to Carson Mint, assay value, \$32,090.67.

OPHIE.—500 level—Jointly with Mexican Co. continue doing necessary repair work in the west drift from the main shaft. 1565 level—The west crosscut started from the bottom of the winze, sunk 52 feet below the sill floor of this level, has been advanced 25 feet; total length, 40 feet; in a porphyry, clay and quartz formation which carries a low assay value.

MEXICAN.—On the 1565 level—West crosscut No. 2 from the north drift from the east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 23 feet; total length, 196 feet, continuing in porphyry formation carrying clay separations. 500 level—Have continued making necessary repairs, jointly with the Ophir Co., in the west drift from the Ophir shaft on this level.

UTAH.—340 level—No. 3 West crosscut from the north drift, from west crosscut No. 2, at a point 195 feet in from its mouth, has been extended 14 feet; total length, 136 feet; in quartzite and clay formation of very low assay value.

SIERRA NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 14 feet, making the total length 326 feet; the face is in hard porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 13 feet, making the total distance west of the joint shaft 3156 feet; the face is in porphyry and streaks of quartz from which there is a strong flow of water.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level, has been advanced the past week 13 feet, making the total distance west of the shaft 3156 feet; the face is in porphyry and streaks of quartz from which there is a strong flow of water.

ANDES.—On 420 level from north drift from east crosscut No. 1 north, a west crosscut has been advanced 11 feet. Total length, 25 feet; formation in quartz and porphyry.

GOULD & CUREY.—200 level—During the past week west crosscut No. 5, started in north-west drift, 432 feet from main west drift, has been advanced 14 feet; total length, 460 feet; face in hard porphyry. Sntro tunnel level—On this level we are now running an east crosscut to make connection between our winze from the 1600 level and the joint north drift.

BEST & BELCHER.—200 level—At a point in north-west drift, 230 feet from our south line, started west crosscut No. 2 and advanced same 18 feet, passing through porphyry and quartz; total length, 60 feet. 900 level—At a point in south-west drift 112 feet from west crosscut No. 3, started west crosscut No. 4, and extended same a distance of 16 feet; total length, 28 feet; face in porphyry and stringers of quartz. Sntro tunnel level—We are now running an east crosscut to make connection between the Gould & Curry winze, which was carried down by them from the 1600 level, and the joint north drift.

HALE & NOECROSS.—1800 level—Have started the new nraise in west crosscut on our south boundary, and are working on the second floor above this level. The top of raise is nearly all in quartz. Main shaft—Have started to retimber at the 1300 level, and are repairing main incline in places where most needed.

CHOLLAR.—Are repairing west crosscut, 450 level, and retimbering the top of main incline 930 level. The east crosscut near the south line, 930 level, is out 172 feet; face is in soft porphyry and clay.

POTOSI.—The north drift from east crosscut, 850 level, is out 34 feet; face is in porphyry and seams of quartz which give low assays. The nraise 80 feet south of Potosi winze, 930 level, is up 60 feet; formation in the top is porphyry. The north drift from east crosscut opposite Potosi winze, 930 level, is out 33 feet, following a 3-foot streak of quartz that gives a

fair assay. The west crosscut from south drift, 930 level, is out 14 feet, following three feet of fair-grade quartz. South raise, 1000 level, is up 20 feet; top shows five feet of fair-grade ore. North raise, 1000 level, is up 43 feet on this stope; formation in porphyry and low-grade quartz. Extracted and sent to mill the past week 541 tons and 1250 pounds of ore from the 550, 930, 1000 and 1150 levels. Milled during the week 540 tons. On hand at mill, 102 tons and 750 pounds. Average battery assays, \$22.80; average car sample assays, \$22.72. Shipped to the U. S. Mint, Cerson, 915 pounds of crude bullion.

ALPHA.—Are putting in guides and retimbering the Ward shaft between the 400 and 1800 levels.

EXCHASQUE.—Are putting in guides and retimbering and repairing the Ward shaft between the 400 and 1800 levels.

WARD SHAFT.—Are putting in guides and retimbering the shaft between the 400 and 1800 levels.

BULLION.—Are putting in guides and retimbering and repairing the Ward shaft between the 400 and 1800 levels.

OCCIDENTAL.—The main north drift on the 750 level has been extended 7 feet. Total length, 750 feet; face is in hard porphyry. The nraise above No. 2 winze in south drift, 750 level, is up to the level of the 650, and we are extending the south drift on the 650 level to connect with said nraise. The Zedig drift has been advanced 13 feet in hard porphyry; total length, 954 feet.

KENTUCK.—We continue to extract from two to three tons of ore per day from the 160 level of the average value of \$31 per ton. On the 1100 level we are extracting ore of fair grade from the stope above the track floor and have extended the main drift south 10 feet. Have started a joint west crosscut in Kentuck ground near the Jacket south line, which is now in 15 feet; face in fair-grade ore.

CON. NEW YORK.—The south drift from the bottom of the winze below the 650 level is in a distance of 37 feet; the face is in quartz, some of which gives fair assays. The south drift from No. 4 west crosscut, 800 level, is in a distance of 54 feet; formation, soft porphyry.

SILVER HILL.—The southeast drift on the 450 level has been advanced 5 feet during the past week, making the total distance from north line 108 feet; the face is in hard porphyry.

Eureka District.

A LUCKY STEIKE.—*Eureka Sentinel*, May 6: Ah Tone, a Chinaman who has mined with good and bad luck in this district for several years, made a rich strike in the Ethel mine, on Hoosac mountain, a few weeks ago. He had from 10 to 15 tons of ore on the dump in the early part of the week, that is stated to be worth from \$250 to \$500 per ton. We are not in a position to give details, but have been told, upon what we consider good authority, that there is considerable of the same kind of ore in sight in the mine. The mine is the property of M. McGerry.

Ferguson District.

MAGNOLIA.—*Pioche Record*, April 27: Six four-horse teams loaded ore from the Magnolia claim last Friday for shipment to Salt Lake. The ore is carefully sorted and no doubt will run high. Meikle, Parthner and Miller have again resumed work on the Jim Crow claim. The recent developments in the Monitor ground, which adjoins the Jim Crow, justify the expectation that pay ore will soon be encountered. Ten teams are on the road with lumber from the Helene sawmill. The bulk of it will be delivered at Pioche, though some goes to Bullionville. This is the first lot of teams to take out lumber in any quantity this spring. A working force of ten men is operating the April Fool mine. Work was suspended some three weeks ago on account of bad air. This is remedied now by putting in air pipes, and a big improvement in the appearance of the mine will soon be made. Harry Lawry and his partners, who recently leased the Reed Mining Co.'s property, have found a rich six-inch streak on the Central claim which runs \$120 in gold and \$40 a ton in silver. It is east of the tunnel and is a different vein to that which the tunnel develops. The steel whim for the Magnolia has arrived and is already in place ready for work. A good ore horse has recently been put on the claim, also. The owners believe firmly in the merits of their property, and are ready to back their faith by investing their cash in it.

Yellow Pine District.

GOON PROSPECTS.—*Pioche Record*, April 27: Nothing but good news is received from the Yellow Pine section of our county, and the mining interest there is gradually growing stronger and promises to develop into a genuine boom before long. There is no longer any doubt but that the Nevada Southern will push its line at once forward to Good Springs, this county, without making any material stop. Thirty miles of rails are now down, which were to have been opened for passenger and freight traffic last week. This brings the line to the Vanderbilt district, where heavier grading for ten miles than any heretofore encountered will retard somewhat the progress of the road. After that point is passed, the 40 miles remaining to Good Springs can easily be laid, since no part of it will require heavy grades, and some 25 miles run over a dry lake, the surface of which is as smooth as a floor and so hard that a band of horses driven over it leave no perceptible trail. The assertion is also made, and confidently, that the building will then continue to be pushed northeastward to the Muddy Valley, thence up Meadow Valley Wash, and ultimately connect with the Rio Grande Western at Salina, Utah. The extension of the road to this vicinity means permanent work for us hereabouts, also, and a resumption of our smelters. With the road in operation to

carry out black ore and iron ore for flintex at other reduction points, and to bring in lead ore from the south in return, there is no reason why good and permanent smelting should not be done here, and it probably will, and when begun on this basis the limit to its extension cannot be estimated. Work on the Yellow Pines mines goes on lightly. The average owner stands ready to furnish ore for shipment as soon as the road will take it, and development work without the road is expensive to such a degree that little of it is being attempted. At the Keystone gold claim not over four men have been employed for the past two months, and no ore has been shipped, though a considerable quantity lies on the dump. Freight rates have been reduced from \$30 to \$15 a ton, and will become lower as the railroad approaches nearer. A new gold mill has just been completed at the Needles, on the Colorado river, in which Mr. Blake of Denver is interested. The next shipments of ore from the Keystone will probably be made to this point, rather than to Denver, as formerly. Taylor's half interest in the property has not yet been purchased, but in all probability it will be before the option expires, which will be on the fifth of next month. The price asked for this interest is \$40,000, and the option is held by Oscar Hibbard, formerly assayer at the Keystone. Development work on the Clementina claim, near the Keystone, is also to be prosecuted now, and Messrs. Keeley, Werner and S. T. Godbe, the owners, are sanguine of making the property more than pay expenses from the start. An offer of \$12,000 was recently made for the claim and refused, though the only work done is a 12-foot shaft. This shows a strong seam of \$560 ore, however, and ore of similar character crops out for more than a hundred feet on the surface, an excellent showing all around.

Aurum District.

SOLD.—*Salt Lake Journal*, April 27: At Aurum, Davis & Sanford have sold their Lucky Deposit to Colorado parties (so I hear), and ten per cent of the purchase price is paid down. Work will soon begin on this valuable property, and it will not be long before the purchasers will reap a rich reward. I am heartily glad that Davis & Sanford have realized on their mine, as they deserve their good fortune for all their years of privation and long waiting.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MAY 2, 1893.

496,717.—GAS ENGINE MOTOR.—Den'l Best, San Leandro, Cal.
496,718.—GAS ENGINE IGNITER.—Dan'l Best, San Leandro, Cal.
496,396.—BOLT CUTTER.—E. Chaquette, S. F.
496,682.—FIRE EXTINGUISHER FOR RAILROAD CAR HEATERS.—J. F. Cowdery, S. F.
496,554.—LABEL.—W. A. Duesbury, S. F.
496,683.—PUMP.—B. Elmore, Biggs, Cal.
496,688.—FAEA RAGISTER.—S. C. Houghton, S. F.
496,689.—STEAM ENGINE.—A. Knudsen, S. F.
496,620.—FEUT PICKER.—I. W. Lord, Cne-monga, Cal.
496,576.—KNOA ATTACHMENT.—Magney & Cate, S. F.
496,530.—BICYCLE STAND.—J. R. McCurdy, Los Angeles, Cal.
496,701.—ELECTRONA.—J. F. & S. J. Sanders, Portland, Or.
496,702.—ELECTRIC ARC LAMP.—J. F. & S. J. Sanders, Portland, Or.
496,620.—CASTOR AXLE AND WHEEL.—A. C. Sanford, The Dalles, Or.
496,712.—RUNNING GEAR.—Warenskjold & Burgess, San Diego, Cal.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

BEAM AND GIRDER SUPPORT.—Francesco Cavallaro, San Jose. No. 495,783. Dated April 13, 1893. This invention relates to a device for supporting the end of beams or girders which abut against other beams or girders at any angles thereto. The object of the invention is to provide an easily adjustable support for the abutting ends of beams or girders where they are attached to other correspondingly shaped beams or girders and at any angle thereto without cutting away or weakening the abutting beams. This device may also be used to support the ends of abutting wooden beams in place of the stirrup ordinarily used.

STEAM BOILER.—Lars A. Olsen, Oakland. No. 495,829. Dated April 13, 1893. This is one of that class of steam boilers in which water tubes with hollow heads are located in the furnace shell, and are surrounded by and communicate with suitable water and steam drums. The invention consists in the novel construction and arrangement of the shell, the inclined water tubes therein, the hollow heads of said tubes, the inclined water drums and the steam drum and feed pipes. The object of the invention is to provide a boiler having a maximum capacity of steam storage, rapid in its steam generation, economical in its fuel consumption, and having great strength and durability.

FRUIT-PITTER.—Enoch W. Weare, Selma, Fresno Co., assignor of two-thirds to E. H.

Tucker of Selma and S. C. Bolling of Alameda. No. 495,860. Dated April 13, 1893. This is one of that class of fruit-pitters in which a vertically moving knife descends upon the fruit, which is snitly supported beneath it. The invention consists essentially in the novel construction and arrangement of the separable spring knives with their expandible pit-receiver, which together form not only a support for the fruit against the action of the upper knife, but also a cutter for the under side of the fruit, a separator for removing the cut flesh from the pit, and a discharger for said pit.

FIELD OF LAWN MOWERS.—David M. Miller, Fairfield, Solano Co. No. 495,825. Dated April 13, 1893. This invention relates to that class of mowers in which the motion of the sickle is derived by power from what is known as a "scroll wheel." The object of the invention is to provide a simple and effective mower for either field or lawn work, having great power, rapidity in operation, and capable of being quickly and easily adjusted and guided.

WATERING-CART.—Harry E. Fairman, Bakersfield, Kern Co. No. 495,792. Dated April 13, 1893. The invention relates to the general class of watering-carts especially adapted for the sprinkling of country roads. It consists essentially in the combination of a traveling wheeled structure, a pump carried thereby and having its suction in communication with an extraneous continuous body of water, such as in a ditch alongside of the road, discharges from said pump to deliver the water upon the road, and power-transmitting connections between the wheeled structure and the pump whereby the latter is operated by the power derived from the traction of the former. The object of the invention is to provide a watering-cart adapted to travel along a road beside a ditch, and having means connected with it for taking the water from the ditch and discharging it upon the road.

CAN BODY MAKING MACHINE.—John H. Murch and James A. Gray, assignors to R. D. Hume, Gold Beach, Or. No. 495,426. Dated April 11, 1893. This apparatus consists of mechanism by which sheets of metal are delivered first to devices by which the edges of the sheets are turned so as to be afterward interlocked and then advanced between a cylindrical horn and an inclosing sheath which forms a cylindrical body, means by which the meeting edges are interlocked, the ends made even and the seams compressed and closed; a device for supplying acid to the seams, a solder trough over which the seam of the can passes, hinged soldering irons so disposed that they dip into the melted solder and are lifted and drawn above the seam as the can passes beneath them so as to hermetically close the seam, after which the can body is delivered complete and ready for further operations.

PENCIL HOLDER AND SHAPE.—Ralph Mazza, San Leandro. No. 496,269. Dated April 25, 1893. This is a pencil holding and sharpening device consisting of a metallic tubular case having an expandible elastic holding end, a conical steel center with closed point and discharge opening near the point, an open slot in the exterior case corresponding with the discharge openings of the center, and an annular disk fitting within the case and surrounding the point whereby the letter is supported and retained centrally within the tube.

AUTOMATIC CAR VENTILATOR.—Thos. L. Merrill, Oakland. No. 496,270. Dated April 25, 1893. The invention relates to the class of ventilators for cars, and consists in an externally located casing communicating through a suitable opening or passage with the interior of the car, and having an automatically operating valve, interior circuits air passages and dust and cinder receptacle. The object of the invention is to provide a means for automatically forcing air into cars, clear of dust and cinders.

SMELTING FURNACE.—Edwin G. Smith and Benj. B. Brewer, S. F. No. 496,235. Dated April 25, 1893. The object of this invention is to provide certain improvements in this class of furnaces whereby the air which is used as a blast is heated in a peculiar manner before being discharged into the furnace through the tuyeres. An improvement is made in the bottom of the furnace whereby there is less loss of heat, and the furnace can be easily and quickly cleaned and overhauled without pulling it down, and the gases and products of combustion are condensed and saved after leaving the furnace.

TAP AND FAUCET.—Mattie Z. Farrington, S. F. No. 496,301. Dated April 25, 1893. The invention relates to that class of taps and faucets in which the permanently seated hushing is controlled by a rotary plug which is operated by the faucet pipe removably engaging therewith. The object of the invention is to provide a simple, economical and effective tap and faucet adapted for use with any liquid-containing vessel, but more especially applicable to beer kegs.

WHEEL FOR SINGLE-TRACK RAILWAYS.—John J. Burt, Tres Pinos, San Benito county, assignor of one-half to M. P. Minor, S. F. No. 496,293. Dated April 25, 1893. This invention is specially based upon the patent granted to David B. James, Oct. 8, 1878, No. 208,738, for a single track railway. The improvement consists in forming the broad single wheels in two independent parts, one of which is moveable upon the shaft, and in mounting the wheels upon swiveling trucks instead of swiveling each wheel independently. The patent also covers certain details of construction. By constructing the wheels with the two independent halves, one of which is movable, the movable portion will yield while the car is passing around short curves and will thus relieve the strain and friction.

tion which would otherwise take place on account of the great width of tread necessary to support and balance the car upon the single track.

TRAVELING HARVESTER.—Benjamin Holt, Stockton. No. 496,311. Dated April 25, 1893. This is an improvement in the apparatus designed to cut, thresh, clean and sack grain. The object of the invention is to enable a traveling harvester and thresher to be used upon sidehills of any description and maintain the frame of the harvester and cleaner at all times in a horizontal position, and at the same time maintain the bearing wheels in a vertical plane. It has also for its object the application of a suitable mechanism by which the position of the bearing wheels with relation to the frame may be changed to suit the varying declivities over which the machine may pass.

TRACE BUCKLE.—Ogden Mallory, Auburn, Plecker Co. No. 496,319. Dated April 25, 1893. The object of this invention is to provide certain improvements in the construction of buckles, links, wear-plates and connecting parts which are used to unite the traces used in light or heavy harness to the main portion of the harness. It consists in certain details of construction whereby the trace-connection between the vehicle and the collar is easily lengthened or shortened; wear-plates are introduced at points where there is a tendency to chafe the trace, and the parts of the buckle are easily dismounted or assembled.

GAS-ENGINE MOTOR FOR CARS.—Daniel Best, San Leandro. No. 496,717. Dated May 2, 1893. The object of this invention is to provide a simple, compact and effective mechanism by which the power of a pair of gas engines may be applied simultaneously to either one of the wheel axles of a car, and a means by which the application of the power to one pair of the wheels will drive the car in one direction and its application to the other pair will drive it in the opposite direction. This improved motor was described and illustrated in the MINING AND SCIENTIFIC PRESS of April 1, 1893.

GAS-ENGINE IGNITER.—Daniel Best, San Leandro. No. 496,718. Dated May 2, 1893. This invention consists of stationary and oscillating arms by which contact is made and broken within the ignition chamber of a gas engine, with means for adjusting the arms with relation to each other. A spring connection is made with one of the arms which allows it to yield, and which returns it instantly to its normal position as soon as the other vibrating arm has passed it. This spring is long and contained in a chamber which is protected from the action of the heat in the explosion chamber, and it does not lose its temper or become distorted.

PUMP.—Benton Elmore, Biggs, Butte county. No. 496,683. Dated May 2, 1893. The invention relates to a pump apparatus in which the body of water to be raised is divided in such a manner that the weights upon each side approximately balance each other. The peculiar form and connection of the two sections of the pump are such that the water is delivered into the top of the pump and a siphonic action is produced when the vacuum is formed by the separation of the two to fill the pump chamber.

STEAM ENGINE.—Augustus Knudsen, S. F. No. 496,689. Dated May 2, 1893. The object of the present invention is to provide an engine in which a crank-shaft extends through the outer casing or cylinder, having cranks in the interior which connect with a moving piston or pistons, and to provide a means for making suitable connection between the fixed crank-shaft, which enters through the sides of the exterior cylinder or case, and the interior parts while maintaining a properly packed joint around the crank-shaft. The application may also be made to a single reciprocating piston, and where two are used the steam may be employed either at high pressure in both cylinders or it may be used expansively from one to the other.

FARE REGISTER.—S. C. Houghton, S. F. No. 496,688. Dated May 2, 1893. The invention relates to that class of fare registers in which a series of periodically rotating disks is operated by means of electrically-actuated mechanisms operated from suitably-disposed switches throughout the car. The object is to provide an accurate, compact, simple, rapid and easily operated machine for registering numbers for any purpose, such, for example, as registering the collection of fares in street cars; also to provide an electrically-operated registering mechanism, and particularly such a mechanism as will be adapted to make both the trip or partial or total registrations required in a machine for use on street cars.

FLAME EXTINGUISHER FOR RAILWAY CAR HEATERS AND LIGHTS.—Jabez F. Cowdery, S. F. No. 496,682. Dated May 2, 1893. The object of the invention is to provide a means for extinguishing the fire in or from a railway car-heater or light, and to extinguish the lights of the gas-burners the moment an accident takes place, thus averting the serious conflagration which so often follows collision and other accidents, and also to make these means entirely automatic and dependent on the impact of the collision or upon the movement of the car in being thrown from the track.

Sampling Works for Sale.

The works are situated at Daguerre, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower engine and 45-horsepower boiler with a 10-ton crusher and other machinery. Mill stones, as ailing outfit, etc., all new and complete. Also upon the premises a fine building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

Market Reports.

The Markets.

SAN FRANCISCO, May 11, 1893.

Postponement of the Monetary Conference until November is announced. It is looked upon as another indication of the President's purpose to call Congress to extra session early in the fall, and has been insisted upon by some of the European delegates to the Conference, so that a definite proposition on the silver question should originate with the United States. The assembling of Congress in extra session to September will afford time for the intentions of that body, in regard to the Sherman law, and the silver question generally to be clearly made known before the meeting of the Conference. It is thought quite possible that, upon the action of Congress, may depend upon the question whether the Congress will reconvene. It is now said that Governor McCreary, of Kentucky, will be unable to serve on the Commission. He has been led to this conclusion, in part by the fact that Mrs. McCreary's health will not permit her accompanying him abroad.

Copper Supplies and Product.

Stocks of copper to Europe on the 1st of May, including quantity afloat, are reported at 52,100 tons, a net decrease of 3000 tons during the month of April. More than one half of the supply is Chile copper. As the product of Chile for 1892 was less than 23,000 tons, it follows that the stock includes a quantity carried over from the previous year. Most of the Chile copper is in England, and some of it must be of inferior quality. France is a small holder of Chile copper. Four years ago she held 31,000 tons, while on the 1st of April, 1893, the stock was only 4875 tons. Recently there have been some heavy transactions in this country in Michigan copper. It is claimed that the Calumet & Hecla Company made a contract last month for the delivery of a large quantity of copper at 11c on the Atlantic seaboard. This quantity has been estimated at 10,000,000 lbs. It may have been more. The sale has steadied the market very materially.

The world's product of copper for 1892 has been estimated as follows in tons of 2240 lbs:

United States, tons	152,636
Spain and Portugal	56,170
Chile	22,565
Japan	18,000
Germany	17,560
Mexico	7,318
Australia	6,500
Cape of Good Hope	5,950
Russia	4,300
Other sources	18,615

Total 1892	310,011
In 1891	277,969
In 1890	268,959

The greatest increase has been in the American product, which for 1891 was 126,839 tons, against 115,669 tons for 1890. Last year this country produced about one-half of the world's copper. The consumption nearly keeps pace with the yield, and prices insure a fair profit to the large producers.

Three Years' Gold Product.

The latest report by the Director of the United States Mint gives the following as the total production of gold by all the mines in the world for the last three calendar years:

1890	\$113,149,600
1891	120,518,800
1892	130,816,600

These figures indicate a steady increase in the production of gold, the gain for the last year being 8 1/2 per cent. Of this increase for 1892 one-fourth part was from the mines of Australasia and the rest from South Africa. The product of the latter reached the total of \$22,069,578 for last year, which is about equal to the gold production of Russia, and makes that region second only to the United States and Australia.

Mining Share Market.

The stock market has not been so active this week as it was last, but still business has been pretty good for the brokers. Mr. Mackay's expected visit to the Comstock has been postponed so he will go to the World's Fair first and then come back to look after the Comstock and Vanderbilt mines. The feature of the week has been the sales in Potosi and Chollar. In the former mine the air connection on the 950-foot level has at last been made so they will be able to go after that six-foot vein of high-grade ore. In this connection the *Report* says: There is this peculiarity about the Comstock market, that a good development of ore in one mine exerts a strengthening influence upon the shares of all other mines along the great lode. Should the developments of ore which are now under way in the Potosi and Chollar mines result as favorable as the friends of those properties think they will, the stock sellers will find it hard to hold the other stocks down, for the public will buy them indiscriminately and without regard to real merits. The higher the prices of Chollar and Potosi advance the greater the demand will become for the other stocks. It is hard to control speculation when it is once started.

Certificate of Copartnership.

WE CERTIFY THAT WE CONSTITUTE A PARTNERSHIP transacting business in this State. Its principal place of business is San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are Samuel B. Connor, residing at San Francisco, California, and Andrew S. Grant, residing at San Francisco, California. SAMUEL B. CONNOR. [SEAL] ANDREW S. GRANT. [SEAL]

July 12, 1890.
State of California, City and County of San Francisco.—ss: On this 12th day of July, in the year one thousand eight hundred and ninety, before me, George T. Knox, a Notary Public in and for said City and County, duly commissioned and sworn, personally appeared Samuel B. Connor and Andrew S. Grant, known to me to be the persons described in, whose names are subscribed to, a deed who executed the within and annexed instrument, and they acknowledged to me that they executed the same.
In witness whereof, I have hereunto set my hand and affixed my Official Seal, the day and year in this Certificate first above written.

GEORGE T. KNOX, Notary Public.

I, M. C. HALEY, County Clerk of the City and County of San Francisco, State of California, and ex-officio Clerk of the Superior Court in and for said City and County, hereby certify the foregoing to be a full, true and correct copy of the original Certificate of Copartnership of Samuel B. Connor and Andrew S. Grant, filed in my office on the 12th day of July, A. D. 1890.
Attest my hand and seal of said Court, this 20th day of April, A. D. 1893.

M. C. HALEY, Clerk. By Wm. H. Lyman, Deputy Clerk.

[Seal of Superior Court.]

NOTICE OF ASSESSMENT.

GOULD AND CURRY SILVER MINING COMPANY.
Location of principal place of business, San Francisco, California. Location of works, Virginia, Storey County, Nevada.

Notice is hereby given, that at a meeting of the Board of Trustees, held on the 1st day of April, 1893, an assessment (No. 71) of Twenty-five cents (25c) per share, was levied upon the capital stock of the corporation, payable immediately in United States gold coin, to the Secretary, at the office of the Company, Room 69 Nevada Block, 309 Montgomery street, San Francisco, California.
Any stock upon which this assessment shall remain unpaid on the 15th day of May, 1893, will be delinquent, and advertised for sale at public auction, and unless payment is made before, will be sold on TUESDAY, the 1st day of June 1893, to pay the delinquent assessment, together with the cost of advertising and expenses of sale.
By order of the Board of Trustees.

ALFRED D. DUNN, Secretary.

Office—No. 69 Nevada Block, 309 Montgomery street, San Francisco, California.

Mining Superintendent.

I am desirous of obtaining a position as Mining Superintendent. I am a graduate of the Columbia School of Mines, and have had 15 years practical experience as superintendent of mines and mill's. Special experience as expert in concentration and amalgamation.

SAN JACINTO ESTATE, LIMITED,
Office of General Manager,
P. O. Address, South Riverside, San Bernardino Co., Cal.
CALICO, Dec. 13, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
I am, my Dear Sirs, Yours faithfully,
S. HARRIS, Manager

STEAM PUMPS.

These Pumps were designed for all services. The Steam Valve Motion is unequalled in any other. All its parts are adjustable to compensate for natural wear, so that there can be no variation in the stroke of the Steam Valves.

The Pumps are made of first-class material and by skilled workmen. They are unusually strong and effective, as has been proved by their long use.

The Boiler Feeders are provided with Removable Brass Valve Seats, Brass Valves and Phosphor Bronze Springs, and, considering the advantages they have, are superior to any other.

The Valve Seats can not get loose, as all are held in place by the top cap. The seats can be removed as all are free when the top bonnet is taken off. These Boiler Feeders require less steam to operate them than any other Duplex Pump. They make full strokes and do not waste steam.

Schools of Assaying and of Mines.

Los Angeles people are agitating the establishment in that city of a school of mines, which it is thought will be of great benefit to the city and at the same time assist in developing properties. It is desired to give instructions in assaying, mining, metallurgy and mining engineering. One gentleman in expressing his desire for the assaying school says it is difficult under existing conditions to get a satisfactory assay of specimens of rock found near Los Angeles, and in some cases it has been necessary to send them to the eastern States, or even to Germany, in order to secure an assay that could be relied upon. Such a statement as that is arrant nonsense. There are dozens of perfectly competent assayers, chemists, analysts and metallurgists in San Francisco, and numbers of them in all the mining towns of this State and coast. Why an eastern assayer should know more than one in a mining region is not apparent. The "rocks" around Los Angeles are no different from any other rocks, and there are doubtless competent assayers in that city who are perfectly reliable. The same wise-acre who has to send East for assays says in relation to the proposed mining school: "Assay work, such as would cost an extravagant sum if sent abroad, could be done at the school at a minimum expense, and at the same time the pupils would have the benefit of the knowledge received from watching it. Instructors of the sort that would be wanted would command large salaries, but he thought that the institution could secure their services at a comparatively small outlay by having them come with the understanding that they should receive a share of what should be paid the school for the assays made."

This is mere nonsense. Teachers would be hard to find who would take, instead of salary, a share of what was received for assay work, especially assay work done by students. If people want valuable assays, such as this man cannot now get in California, they assuredly would not expect them from young men and boys learning the business. They would go to experienced men.

Moreover, an establishment for teaching assaying is not usually called a "School of Mines." There are half a dozen or more such places in San Francisco, and there are now more assayers than can find places. The editor of this paper only last week sent an assayer to a mine where he is to receive but \$50 a month and board, and there were half

a dozen ready to take the job. Nearly all the big mines have their own assayers, and in every camp there are several.

None of the gentlemen interviewed by the Los Angeles paper appear to have been aware of the fact that there is now a school of mines supported by the State of California and in full operation, free to any one who wishes to enter. At the University of California is a department of mining and metallurgy, one of chemistry and one of geology and mineralogy.

Not only is assaying taught, but analysis of ores, geology, mineralogy, mine surveying, mining engineering, mining and metallurgy. All the necessary appliances are provided, including a stamp-mill, concentrators and other

Freight on Street Railways.

The city attorney of the town of Colton, San Bernardino county, has reported to the Council that the Southern California motor road had a franchise only as a street railway and cannot use steam nor haul freight. The attorney was instructed to prevent the hauling of freight in the future. Doubtless many other street railroads are in the same legal fix, and it would be to somebody's interest to prevent them hauling freight. This being the case, it will be well for all those asking franchises in the future to mention the freight, so that they may be permitted to carry it if desirable.

Most suburban roads, whatever their power, could be made more useful and profitable if they could carry freight. Even in large cities, like San Francisco, the cable roads, which reach in every direction, could carry freight at night to advantage by having suitable cars. Thousands of tons of freight landed from ships or cars could be transported from wharves or depots, back to the populous settlements of the city. It would be much cheaper to do this on the cable roads than by teams. No provision was made for freight, however, in the franchises, and the powerful teaming interest of the city prevents the roads doing anything but a passenger business.

In the country,

however, and on suburban routes provision should be made for transporting freight and merchandise as well as passengers. It would be for the interests of each community, but in asking for passenger franchises the companies have overlooked the possibilities of the freight proposition. Some of these roads run for many miles out back of the cities and towns and could carry supplies which now have to be hauled by teams.

Public policy would seem to demand some legislation which would permit these roads to carry freight and merchandise if they desired to do so. The roads are for the convenience of the public and the present restrictions are in the direction of maintaining high rates on supplies. With the poor country roads now prevalent teaming is comparatively expensive and slow. But well-equipped electric roads would deliver supplies, merchandise and take back products as well as carry passengers. This would benefit the public by cheapening cost and furnishing a means of quick delivery, and it seems absurd that some little legal technicality should prevent the use of the electric cars for this purpose.

BROWN-ALLEN IMPROVED O'HARRA ROASTING FURNACE. (See page 307.)

mining machinery. These facilities are open to students from any part of the State. There is a magnificent typical collection of rocks, ores, minerals, crystals, etc., for the use of students.

With such an institution in full operation we can see no need of a school of mines at Los Angeles. If it is necessary to teach the local youth assaying an assaying school is readily formed, but to create a complete school of mines and equip it, is no small matter. Moreover, while there are, of course, plenty of mines in southern California, there is not one there where there are a hundred north of San Francisco. Those young men who want to equip themselves as mining engineers and metallurgists can do so without cost at the University of California. Hundreds are doing this and are following the profession now. But the mere learning to assay amounts to very little and in these days does not pay, unless some other branch is combined with it.

THE profit to Chicago from its water-works for the last fiscal year was \$1,389,854.

Comment.

From the letter of a correspondent of the PRESS, published on page 309, it will be seen that Los Angeles will shortly have a smelter in operation. Ores are to be purchased by the company which will be a good thing for those owning mining properties. There are mining claims in that region which have remained undeveloped because it has cost too much to ship ores to smelting works in this city, but with such works near at hand, the mines can now be worked. A testing plant for the cyanide process is also being put up at Los Angeles, which is more than has been done in this city, though the company at Denver, owning the patents, have been asked to establish a branch here, where ores could be tested. It will now be in order for the Los Angeles capitalists to help the miners out in developing their properties, but if they keep their pockets buttoned, the miners will be helpless. It takes money to open and start mines up, and few prospectors have any. When once the mine is properly opened, if it is any good at all, it can keep itself running all right.

On another page is a well-written description of one of the big mines of Shasta county—the Texas Consolidated. Mr. Barnes, who wrote the article, is a mine-owner himself and a conservative man. It is probable he is slightly in error, however, about the amount of ore delivered by the Hallidie tramway with the buckets 160 feet apart. It is more likely they are 120 feet apart on the rope. The statement about there being very little dead-work in the mine requires modification also, as, if memory serves us, there are some 3000 or 4000 feet of bedrock tunnel—all in barren ground. In the fourth paragraph, where the "width of two chains" is spoken of, the types should have read two "claims." Mr. Hart, the owner of this mine, is a very enterprising man, and deserves his good luck in getting such property. It has paid him so well that he has also bought and opened the Cleveland Consolidated, or Bullychoop group, on the Bullychoop divide. Here a cyanide plant is to be used. There is a very large deposit of ore, and Mr. Hart expects the new property to be very profitable. If it does as well as the Texas Consolidated, he will have nothing to complain of.

An accident happened this week at the vertical shaft of the Calumet & Hecla mine, Michigan, by which ten miners were instantly killed. The engineer hoisted the cage "into the sheaves" and the men and cage were dashed downward 3000 feet. The bodies were torn to pieces and had to be carried to the surface in canvas sacks. The engineer says the indicator failed to work and he did not know that the cage was at the surface. There are so very many mechanical appliances for the prevention of this particular kind of accident, which was

formerly so common, that no big mine like the Calumet & Hecla should be without them. They should not depend on the indicator alone, as seems to have been the case in this instance. Any one of a dozen appliances would have informed the engineer or would have automatically shut off the steam as soon as the cage came above the shaft-mouth. An investigation will take place, of course, and the responsibility fixed. When there are well-known appliances to prevent such accidents and the managers fail to supply them they should suffer exemplary damages.

In the PRESS a week or so ago, mention was made of the resignation of Mr. Edward Coleman as superintendent of the Idaho mine, and the appointment of Mr. Eugene Oreller in his place. From a long practical training, no one is perhaps better fitted to fill the place than Mr. Oreller. The leaving of Grass Valley by the Coleman brothers must be a matter of great regret to all who feel interested in the welfare of the place. No individual or company has done anything approaching the good the Coleman brothers have done for that place in every way. In February, 1860, they purchased the old North Star mine, made a great success of it, sold out and commenced developing the Idaho mine, which has proved to be the richest gold mine on the Pacific Coast, having paid handsome dividends for the past 23 years. Through them, the branch railroad was made from Colfax to Grass Valley and Nevada City, and they were largely instrumental in bringing in the water supply for working the different mines. These gentlemen have been identified with industrial and mining matters in Grass Valley for a great many years, and the life they have lived has earned for them the respect of the entire community. They now have large interests in San Francisco and will probably reside here in the future.

In the MINING AND SCIENTIFIC PRESS of last week reference was made to the utilization of the magnetic-iron sands on our sea-beaches, by magnetic separators, as is being done elsewhere. Since then we learn from the Del Norte Record that a plant is being put up on the beach fronting Crescent City, with which they expect to handle 1000 tons of sand per day and obtain 100 tons of iron, to be shipped to this city for smelting. The plant referred to belongs to the Lawson-Rice syndicate, and is in charge of Mr. Arkew, who is the inventor of the process of manufacturing iron from black sand by the aid of electricity. The *modus operandi* by which the sand is operated and converted into iron is not known, but the claim is made that if the sand will yield 10 per cent iron, it can be worked profitably. The company is already getting its plant moved to the ground where operation will be commenced, and will receive by the next steamer a new engine and boiler which will be used for running the dynamo; the smaller engine will be used for pumping and running the cable for carrying sand. It expects to have the plant in working operation before the first of June, and when running will employ about 30 men. In the employ of the company are Messrs. Henry and Paul Raymond, who were at Crescent City several years ago, running a gold-saving machine on the beach. The company has already in operation in Oregon a plant for the reduction of ores by electricity, and should this one at Crescent City come up to the expectations of the inventor, the company will no doubt put up a larger plant.

The appointment of John Daggett, owner of the famous Black Bear mine, Siskiyou county, as superintendent of the U. S. Branch Mint in this city is a victory for the miners of California, all of whom, regardless of political affiliations, united in an effort on his behalf. While Mr. Daggett has played an important part in the development of the mining interests of the northern section of the State, his efforts have not been confined entirely to that district. For a number of years he has been a part owner in the Calico mines in southern California and has greatly aided in developing them. He is also interested in land transactions throughout the State. Mr. Daggett has always been more or less in politics. In 1859 and 1860 he served the State as a legislator. He was chosen to represent the district composed of Del Norte and Humboldt counties. In 1882 Mr. Daggett received the Democratic nomination for Lieutenant Governor of the State and was placed upon the same ticket with Governor George Stoneman. Upon the expiration of Mr. Daggett's term as Lieutenant-Governor, he deserted the political arena and devoted his energies to the development of his private interests until 1891, when he was appointed a World's Fair Director. It is the duty of the superintendent of the Mint in this city to collect annually the statistics of production of precious metals on this coast and to prepare the descriptive chapters setting forth the condition of the gold and silver mining industry. Until now we have never had a mint superintendent who took any special

interest in this branch of his duties or knew much about it. Mr. Daggett, however, from his long experience in mining, will doubtless prepare reports which will be of service to the mining community.

Of chief interest among the events of the week is the affirmation by the United States Supreme Court of the Geary act, relating to Chinese residents of this country. By this decision it is held that it is perfectly competent for the legislative branch of the government to compel the registration of any class of aliens and to prescribe the penalty of deportation for the refusal or neglect to comply with the law. It will be remembered that this act was passed by Congress a year ago and that one year was given for the Chinese to comply with it. All who have not complied with it (and they number nineteen-twentieths of all the Chinese in the country) are now liable under the law to arrest and deportation.

On the basis of this decision, it has been hastily assumed by anti-Chinese enthusiasts that within a few weeks all the Chinamen in California will be bundled back to their own country, but this is the wildest sort of folly. It is, in fact, a thing physically impossible. The Chinese failed to comply with the law under the theory that it was not constitutional. Now that it is demonstrated to be constitutional, they will no doubt comply with it. Congress will, of course, extend the time for registration.

It is estimated that there are 80,000 Chinamen subject to arrest and deportation under the law, but it provided that in each case the delinquent must be brought before a United States Court, that his delinquency must be proved and that judgment of deportation must be rendered against him personally. If our courts were to devote their whole time to cases of this kind they could not dispatch one thousand per month. Furthermore, it is estimated that to send 80,000 persons to China would cost at least six millions of dollars, whereas there is available for carrying into effect the Geary law less than sixteen thousand dollars. Clearly the job is out of proportion to the means. Nothing can be done until Congress meets, and then no doubt time will be provided to enable the Chinese to comply with the law. In fact, the purpose of the Geary law was not to send away the Chinese now here, but to provide a means for detecting or identifying Chinese unlawfully present in this country. A little patience will accomplish all this.

Edward O. Leech, Director of the Mint, has resigned to become cashier of the National Union Bank of New York, to be opened June 1st. Doubtless Mr. Leech will make a better bank cashier than Mint Director. This gentleman was always held up in Washington as an example of the failure of the plan of promoting a subordinate to chief of a division. He always used to speak of "my mint," "my report," etc. Originally brought into the Mint Department because he was a good baseball player and because he was wanted in a mine, he kept there, and has been for some years chief of the Mint Bureau. In his annual reports he never specified the difference between his own estimates of gold and silver production and the exact returns gathered by the statisticians of his department. The result is that one will find on one page the total production of a State and a few pages further on an entirely different total—the latter being usually the Mint Director's "guess." There is nothing said about one set of figures being actual returns and the other an estimate. The attention of Mr. Leech has been called to these discrepancies but as he supposed all knowledge of such things was confined to himself he has continued the practice. Another practice established and continued by Mr. Leech is that of sending out circulars asking for returns of bullion product of mines and stating that the information furnished will be considered confidential and only used in making up the totals of the States. Yet when the report appears the name of every mine appears with its respective figures of production. This habit has also been called to Mr. Leech's attention, yet he continued it. However, many mine-owners now decline to furnish the information, so Mr. Leech has more scope for his guesses, as he calls the estimates which appear in his report. It is to be hoped that this gentleman's successor will at least keep faith with those furnishing him information, and, if he promises to keep confidential these figures, will not publish them. If the new man does this he will be apt to get out a much more accurate and reliable report of the bullion production of the country than Mr. Leech has been able to do.

THOMAS MEIN, the California miner, who is superintending the Robinson gold mines in South Africa, has reason to feel proud. The company, at its last meeting, voted him a present of \$2500 besides his annual salary. The company evidently knows a competent man when it sees him.

Mineral Exhibits at Fairs.

In the matter of making displays at exhibitions and fairs, more seems to depend upon the efforts of the individuals managing it, than upon the amount of money they have to spend. A few energetic, active men will accomplish greater results, with a small amount of money, than a large "show" committee with ample funds. At the time of the Paris Exposition in 1878, at a meeting of citizens a commission was appointed to collect and display an exhibit to represent the mining industry. An executive committee was appointed in this city, consisting of Almarin B. Paul, Henry G. Hanks, J. P. Jackson, Melville Attwood, A. Deere, Dr. E. J. Fraser and Sol. Heydenfeldt, Jr. The legislature refused to give any money whatever, and as those gentlemen had been collecting many specimens they were at a loss what to do. Mr. John W. Mackay, who was in Virginia City at the time, reading of the matter in the papers, sent Mr. Attwood a check for \$5,500 to be devoted to the mineral display, asking also, that his name should not be mentioned. With this money they went to work and made a few collections, and Mr. H. G. Hanks was sent with it to Paris. None of the committee received any salaries, and only one of them, Mr. Hanks, went to Paris, his expenses being paid. The exhibit made attracted much attention and a medal was awarded it.

Here was a case where a few active, intelligent men accomplished good results. In the matter of our State mineral exhibit at Chicago, the Commission set aside \$15,000, but, judging from the reports of Chicago correspondents, it is by no means what it should have been. The letters of the correspondents have, however, had a good effect, for many more specimens have since been sent on by express, showing that the original collection was deficient, as charged. Most of that lately sent relates to the gold-mining industry, the leading one of this State.

The delay in the preparation of the building and the exhibit has been injurious to the interests of California, and the people here are indignant that it should have occurred, after having provided, long in advance, abundant means. The trouble has been, apparently, that there has been more consideration as to who should receive salaries than as to who was capable of doing the work. The mineral exhibit has come in for some sharp criticism, but this has done good, for, as stated, many additional specimens have recently been forwarded.

TWO MILES above Lake City, on Perry creek, which empties into the North Fork of New river, Trinity county, Steve Noble and his sons have been mining all winter by ground sluicing. The gold they obtain is all coarse, the pieces ranging from one to thirty dollars, the latter being the value of the largest piece found by them the present season. That it is paying well is evidenced by the fact that they in one day have taken out as high as \$75 in nuggets during the winter's run.

THE shaft in the McCarthy cinnabar mine has been sunk to the depth of 33 feet, and the superintendent of the works, Captain Hook, started a crosscut to run 35 feet northwesterly. It is anticipated that this will be a sufficient boring to determine whether it will be profitable to continue the mine as an ore-producing proposition or to abandon it and convert it into ordinary suburban real estate. It will probably be suburban real estate.

THE revised plans and specifications for the new union ferry depot make the building 150 feet wide by 666 feet long. Ninety feet was taken off each end of the original plans for the time being. Chief Engineer Holmes claims that \$25,000 in cement has been saved the State by the delay in letting the contract. Experiments were made which proved that the original foundation plans for concrete were heavier than really needed.

THE appraisers of the estate of the late Henry Martin, of Deadwood, Trinity Co., have placed its value at \$220,320. They value the one-third interest in the Brown Bear mine at \$40,000, but most miners will think it worth more than that. Mr. Martin, among other things, had \$63,210 cash on hand. He made all his money out of the Brown Bear mine.

MESSERS, FRASER & CHALMERS, the Chicago mining-machinery manufacturers, have an exhibit at the World's Fair occupying 6060 feet in the southeast corner of the Mines and Mining building. They also have a triple-expansion 1000-horse power Corliss engine in Machinery hall.

THE interest in the mines of the Colorado is increasing daily and much gold is being taken out. The steamer Gila has left Yuma with 156 carloads of pipe and other freight for the Picacho placers. It is proposed to put in a pipe line from the Colorado river, to furnish water for washing the dirt.

The Brown-Allen O'Harra Roasting Furnace.

The furnace illustrated on page 305 is an improved form of the O'Harra furnace, which has been in use for some years. The improvements consist essentially in the perfection of mechanical details, and in the protection of the working mechanism from heat and fumes.

As originally constructed, the O'Harra furnace consisted of a double hearth reverberatory with extensions on either end for carrying shafting and pulleys. Round these pulleys a chain was passed, forming an endless belt to which stirrers were attached. These stirrers, which consisted of triangular frames having suitable blades or points, rested directly on the hearth of the furnace. Motion was communicated to the chains by suitable power, and the stirrers were by this means dragged through the furnace. The driving chain passed through the center of hearth where the heat was most intense and was consequently subjected to so great a heat as to soften it, and cause it frequently to part in the weld. It was also exposed to great wear by attrition from running over hot pulp. The stirrers resting on the brick hearth rapidly cut it away and wore themselves out, causing great friction and strain upon the chain, which was injured by the heat and wear.

This combination of disadvantages neutralized the otherwise excellent working of the furnace.

The first improvement made on the furnace was by placing cast iron tracks through the hearth and mounting the stirrers on wheels. This revolutionized the desulphurizing of ores by mechanical stirring, as the friction was so much less that an increased number of stirrers could be used, thereby increasing the duty of the furnace, and the wear was so much less that the stoppages were reduced so that the furnace could be kept at work a much larger period of the entire time.

By additional improvements the construction of the furnace has been so modified as to place all of the tracks and moving mechanism outside of a slotted wall or partition, thereby protecting them completely from the injurious effects of the heat and fumes. Supported by the wheeled carriers and projecting through the slotted wall of the partition, is an arm carrying the stirrer blades. This arm is rigidly supported by the weight of the wheeled carriers, so that the stirrer blades do not touch the bottom of the hearth. This construction reduces the friction to a minimum and obviates all the troubles from excess of heat heretofore experienced in stirring mechanically. The duty of the furnace has been increased from 15 tons per day to an average of about 40 tons, without increasing its size. The general features of construction will be readily understood by reference to the cut, which exhibits an elevation of the furnace with the side walls broken away to show the passages for the heat and gases, and the general arrangement of the fire boxes for the two hearths. The distinctive feature of the furnace, as regards protection of the moving mechanism by the slotted wall in partition, is plainly shown in the cross section.

It has long been considered that the reverberatory form of furnace was the best known means for desulphurizing or chloridizing ores, the only drawback to such furnaces being the expense of hand stirring. By the improvements which have been made and are now incorporated in the O'Harra furnace, this objection is entirely obviated and it has become one of the most reliable and effective furnaces in use. There are now 22 of this class of furnace in use, giving the most perfect satisfaction as regards the amount and quality of work being done. As compared with hand-roasting, the cost of roasting on the improved O'Harra is about one-fourth, with a corresponding saving in the amount of fuel per ton and in losses by dust and volatilization. In the improved O'Harra the heat is so evenly distributed that no portions of the ores get overheated, so that the operation of burning off the sulphur and final breaking up of the sulphates can be carried on with a minimum heat, and consequently a minimum loss from volatilization. Experience has demonstrated that this distribution of heat is a great advantage, and also, that the action of the furnace is so gentle and regular that no dust is raised in stirring, which is a very important feature. In practice the entire charge is stirred about twice each minute, so that as compared with hand-roasting, the stirring is constant, and in point of time and efficiency the results approximate very closely to muffle roasting. The furnace admits of being so modified as to be thoroughly adapted to the nature of the work to be done.

By referring to the cut, the operation of the furnace will be understood as follows:

The ore is dumped into a hopper from a car, as shown, and is fed automatically into the furnace, the amount fed being regulated by weight, as may be desired. The ore is gradually drawn through the furnace by the action of the stirrers on the upper hearth, to an opening close to the rear end, where it drops down to the lower hearth. The stirrers pass out through a suitable doorway and in travel-

ing the length of the extension floor, out and back, become so far cooled as to neutralize the effects of any heat which has been absorbed during the passage through the furnace. In passing through the lower hearth, the stirrers again take up the ore and gradually work it forward until it is discharged. There are six stirrers on each side, the two sides working independently, and the stirring operation is carried on at the rate of two operations each minute, so that every portion of the ore is exposed to the action of the heat and oxygen, almost continuously, resulting in a very perfect and rapid roasting of the material. The arrangement is such that the ore travels against the heat and gradually works towards the hottest end of the furnace, which is the rational proceeding in desulphurizing ores, as when the sulphur is nearly all eliminated the heat must be increased to keep up the operation. From the fact that the working mechanism is protected, and the stirrers are so much of the time in the open air at the two ends of the furnace, no amount of heat can be generated in the furnace that will have a destructive effect upon the machinery, and the charge being stirred so continually, the most fusible metals do not have any tendency to ball or form accretions on the hearth as is the case with hand stirring in which the charges are only moved occasionally.

This furnace is particularly adapted for chloridizing silver ores, and, in fact, was originally designed for this purpose only. Where there is but little sulphur in the ore to be chloridized the salt and ores are fed together and worked through the furnace, but where there is considerable sulphur that needs to be burnt off before the salt is fed, the desulphurizing process is done on the upper hearth and the salt is fed to the ores on the lower hearth. The makers of the furnace, Messrs. Fraser & Chalmers, of Chicago, have also an automatic feeder for feeding salt, which can be built into the furnace at any desired point over the lower hearth, so that the salt can be admitted as desired. Owing to the constant stirring and thorough exposure to the heat, a much better chlorination is obtained than by the usual practice, and with a minimum amount of salt.

From 50 to 60 tons per day can be chloridized in one of these furnaces at an expense for fuel and labor of about 50 cents per ton. Another important feature in chloridizing ores which of necessity are crushed fine, is the small amount of dust that is raised. The action of the stirrer is so uniform and gentle that no dust is raised by the stirring, and the only point where dust is formed is where the ores fall from the upper hearth to the lower hearth. From the passage between the upper and lower hearth to the flue entering the stack, the distance is so great that nearly all of the dust settles before reaching that point.

One of these furnaces was put in where revolving cylinders had been used, and the amount of dust collected upon cleaning up the dust chamber was just one-tenth of what had been previously collected from the cylinders in the same length of time. The arch of this improved furnace is so high above the ore bin that the draft following the roof is not strong enough to create any dust, so that no dust is formed except as above noted.

There is no duty which can be required of any furnace in the way of roasting or chloridizing any class of ore to which this furnace cannot be adapted, except in cases where it is required to actually sinter the ore together. Where sintering is required an auxiliary hearth is constructed, into which the calcined ores are discharged by the machinery, and the work on the sintering hearth is done by hand.

Foundry Notes.

The Risdon Iron Works report business brisk in Heine patent safety water-tube boilers and Bryan quartz mills. They are also making a good many sales of the Hawley smoke-consuming furnace. Several have been put in new boiler plants in this city, and the results justify their use both in economy and prevention of smoke. One of these appliances is in use in connection with the boilers at the Risdon Works, and, although a very common grade of coal is used, there seems to be a perfect combustion, as no smoke comes from the stack.

These works provided for the Alameda Electric Railroad, which has just started up, 250-horse power compound tandem Ball engines, Conover condensers and Davidson pump. They have recently commenced the manufacture of the Johnson ore concentrator, and six of these machines are in course of construction in the shop, to be sent to mines in different parts of California. We shall give a detailed description of the new concentrator in the PRESS of next week.

Like most of the foundries in this city, the Risdon has more or less machinery, etc., on the sidewalk around the works. This is now being cleaned up, painted and utilized for advertising by having the name of the article painted thereon.

Coast Industrial Notes.

UPON report of the State Prison Commission's engineer, W. R. Eckart, the machinery in the new jute mill has been accepted and the contractor's bill for \$38,442 ordered paid.

THE directors of the San Antonio Water Company have voted to call an election of the stockholders to vote bonds for \$500,000 for the purpose of purchasing additional water to double the present supply of Ontario.

THE right of way for the Southern Pacific railway into Riverside has been fully secured and construction will probably be begun soon. The new line will run from Colton, via Riverside, Pomona and Monrovia, to Los Angeles.

IN the boilers of the stern-wheel steamer Frank Silva are completed on time the new Whitney Express between this city and Oakland will be in operation by Monday next. It is generally believed that the opening of this ferry will be the signal for a general cut.

IT is reported that the Southern Pacific will begin the construction of the Black Canyon line, surveyed over a year ago, to connect the Maricopa and Phoenix line with the Bullock road, a distance of 110 miles, from Phoenix to Prescott. Recent estimates show that three-fourths of the freight and passengers coming into Phoenix now pass over the Santa Fe line to Deming, most of which will come from the north when the new line is completed.

REPRESENTATIVE CAMINETTI is trying, before going back to California, to induce the members of the House Committee on Rivers and Harbors to go with the Senate sub-committee to the Pacific coast to select a proper site for the proposed deep-water harbor in the vicinity of Los Angeles. By having both houses of Congress represented in the party making the trip, the chances would be better for legislation next session favorable to California rivers and harbors.

AT last Oakland and Alameda are joined by an electric road, for the Oakland, Alameda and Piedmont Railroad Company is now in regular operation. The line runs from Broadway and Seventh streets in Oakland, down Broadway to First, then across the Alameda marsh by way of Webster street to Santa Clara avenue in Alameda, and up that thoroughfare to Park street; thence along the latter street to the Twenty-third Avenue Station of the broad-gauge train in East Oakland. The electric service is a great improvement over the days when it took nearly an hour to go to Park street in the old horse-cars—those antiquities of a past age. The cars are making regular and profitable trips.

NEARLY 200 retail merchants of the Willamette Valley, Oregon, are expected to arrive in this city on May 27th. The object of their visit is to ascertain what inducements San Francisco can offer to secure the trade of that part of the country. Prior to the adoption of the high tariff of the Southern Pacific the bulk of the buying in Oregon was done here, and hundreds of thousands of dollars were spent annually in California. The Oregon Pacific and the Willamette Valley and Coast Railroads have recently changed hands, the result being a decided cut in rates from this city. The merchants, realizing the advantage of purchasing in California, decided to lay the matter before the Board of Trade of this city.

THE work of driving piles for the ferry pier of the California and Nevada Road at Emeryville will commence soon, a new engine for the driver having been completed. President Emery says that it was expected to complete the construction of the pier and the throwing of the road from a narrow to a broad gauge in about eight months. The contracts for all the material and for the new rolling stock have been let. The pier is to run parallel with that of the Southern Pacific at Oakland, and will be in direct line with Goat Island. When the pier shall have reached a point where the water is of sufficient depth to permit, a boat will probably be chartered to serve as a temporary ferry until the two large and speedy boats shall have been built.

THE Secretary of the Painters' Union at Los Angeles writes to the *Examiner* as follows: "There have appeared advertisements in the San Francisco papers for laborers and mechanics for this city. The local press, real estate agents and contractors are endeavoring to create the impression that there is a boom in Los Angeles and that there is a scarcity of mechanics in the building trades. Such is not the case, as any well-informed mechanic will tell you; it has been the dulllest winter for several years. There have been and are at present hundreds of idle men, especially among the painters, of whose condition I am better informed. They have not, and are not now working more than half the time, and they are still coming in from all parts of the country."

THE Harbor Commissioners at their meeting Tuesday afternoon opened bids for the construction of the foundation of the new ferry buildings at the foot of Market street. The plans and specifications were lately revised. The contract was awarded to the San Francisco Bridge Company for \$247,837, it being the lowest bid. Bateman Brothers, whose bid of \$328,500 on the original plans was refused, filed a protest against the award of the contract. There were eight bids presented to the board as follows: Bigelow & Fogg, \$346,000; California Bridge Company, \$337,767; Doe, Hunt & Co., \$297,000; McCann, McKay & Phillips, \$290,000; McMahon & Son, \$295,000; Catton Brothers, \$317,227; and Healy, Tibbets & Co., \$309,000. The San Francisco Bridge Company's bid was over \$40,000 under that of McCann & Co., who were next to the lowest bidders. The bonds required amount to \$130,000 and will be filed this week. "We are glad to have the contract let," said Commissioner Cole, "and hope to see the work on the foundation progressing within the next ninety days. Until ferry slips 3 and 4 are completed by the McMahons, the present contractors, very little can be done on the work just yet."

Something About Placer Values.

IT is an undeniable fact that the hunt for gold properties for the past few years has not kept pace with that for silver. Now that silver-lead has a "black eye," the inquiry for gold becomes greater and already the festive prospector announces while seeking for some one to grub stake him, "that he is going to look for gold, be it placer or quartz." Throughout the mountain ranges within easy range of this city are thousands of acres of gold-bearing placer which could be made productive if worked to the best advantage and by the best methods. There may be a recurrence of discoveries such as Alder gulch, Last Chance and Boise basin, but we do not deem it probable; those picnics have had their day, and the man who reports that he has discovered placer that prospects twenty-five cents to the pan from grass roots may safely be set down as a mining camp liar, whereas if the statement made would call it one cent to the pan for an average it would be under proper conditions of working a good thing.

IN support of this we will figure up what that prospect would amount to for a cubic yard. Allow three pans of dirt to the cubic foot and you have eighty-one pans or that many cents to the cubic yard. Admitting that conditions are favorable for working and a claim using one pipe head of water will employ seven men for twenty-four hours, making the cost of running the claim about twenty-five dollars per day; this will count wages, wear, tear and repair of tools. These men ought to have deposited in the box each day gold dust valued at the lowest calculations \$175, or a profit of \$150, by hydraulic methods. Beginning work on April 15th and ending November 1st there should be, less stoppages for various purposes, 190 days of actual placer mining in our northern country, which would give a profit of \$28,500. The placer miner who reads this will exclaim at once, "there are not a dozen placer claims in the whole country that pay this figure." Why not? Because this estimate is made on the hypothesis that the ground is already open with an abundance of water and dump, ditches and reservoirs made, pipe, giant and flume all in place and everything in working order, and that the ground actually gives an average prospect of one cent per pan from the grass roots to bed rock, and that the miner picks down three times as much dirt as he would pick and shovel into the boxes. Even give an average of one-half a cent per pan on this basis and the income is a good healthy one and would be very gratifying to the majority of placer workers.

This estimate is made to show the folly of listening to men who come in with stories about having ground that prospects twenty-five cents to the pan where water and dump are convenient. The writer has seen \$11 panned out on the point of a shovel, and as high as \$110 to the pan on the bed rock, yet the claim only averaged three cents to the pan from the grass roots to the bed rock, and it was considered very rich ground by old-time miners, and it was; it paid enormous profits working it old style with a pick and shovel, mud boxes and sluices with slight head of water, and wages five dollars per day.

NO better investment exists at the present than to work placer grounds under favorable conditions of water and dump that will average one-half a cent to the pan, from surface to bed rock, where there is large enough body of ground to insure steady work during the placer season for a term of years. There is no question that there are large areas of ground in the Northwest that will pay handsome returns on the capital invested to open the ground that will not average one-half cent to the pan; but do not be misled by exaggerated statements of ten to twenty-five cents per pan into making foolish investments; such ground only exists in the imagination of the mining sharp looking for suckers.

THERE is no better time than the coming season to look for and secure tracts of placer territory, which, if properly opened and worked, will give an assured and comfortable income for years to come. Then the nation needs gold which, thanks to our able-bodied law makers, is the only money we have, and who obey the behests of Wall street in preference to the will of the people.—O. C. in Northwest Mining Review.

BUTTE COUNTY MINES.—The mining resources of this county are scarcely known. The clays, iron, copper and other minerals besides gold are entirely undeveloped. Near Wyandotte, twenty years ago, there was a great mining excitement over copper and a number of ledges were discovered. When the country is more populous and the railroad facilities better, these ledges will be worked. There are half a dozen places in the county where rich and extensive beds of iron ore are found. There is no finer marble in the United States than can be found in Butte. Silver is not wanting, and so with a number of other metals. The royal metal, king gold, is being found in ledges now more extensively than ever before known in the county, mills are going up in every section, and there is an activity and a bonum that promises to put more life and vim into Butte than we have witnessed these thirty years. Our mining resources are immense and are as yet practically undeveloped.—Oroville Register.

CALIFORNIA STATE MINERS' ASSOCIATION.—The miners of California should bear in mind that it is only thorough organized effort that any good results can be accomplished. They now, for the first time in the history of California, have a thoroughly equipped organization, officered by able and trustworthy men. The State Miners' Association has accomplished much and can accomplish much more if the proper support be given it by the residents of the mining counties. True, the association has been deceived and betrayed in some instances where the association had a right to expect better treatment, but the association itself has always been on the right road and has done much toward moulding public opinion and preparing for legal victories. The Anti-Debris Association, with which the miners have to contend, has a thorough and complete organization with a full complement of paid officers, agents

and attorneys. The Anti-Debris Association has an income from the various counties through which it extends of over \$2000 a month. It has a salaried manager, a paid attorney and numerous paid agents or spies. To meet the work of this organization the miners must support their own association. So far, the miners have contributed but lightly to the funds of the association, while the greater portion of the moneys heretofore raised by the association has been voluntary contributions by the business houses of San Francisco. The miners must show their appreciation of the help received or they will lose the friendship and support of their natural allies in the commercial world. The miners are now passing through a critical period and must be thoroughly united to secure ultimate victory. Stand by your State Association—miners of California.—Mountain Messenger (Sierra county.)

River Bed Mining.

A somewhat curious experiment in river mining is now being made with flattering success in Shasta county. For a distance of nine or ten miles up-stream from Redding the Sacramento river-bed is rich in gravel gold. In early days this district, embracing both sides of the river, was one of the richest diggings in California. All of the creeks and water channels putting into the river thereabout carry more or less gold and during the placer mining era when the beds of these water courses were raked over and over for treasure, the river finally received the gold, which the miners disturbed but failed to get. By means of wing-dams and other devices the river-bed itself has yielded many thousands of dollars in dust, but there are places and spots that could not be wing-dammed, which are rich with the spoils of centuries of wash.

J. W. Brackett, a former resident of Shasta county, states that the Diestlehorst brothers, who own a farm on the river bank, close to Redding, have rigged up a crude dredger with which to work the rich spots in the river. The boat is decked over and carries an engine which is utilized for several purposes the chief of which are to operate the dredging apparatus and to move the boat. When it is necessary to proceed further up-stream, a line is carried up the river several hundred yards and made fast, and a steam windlass does the rest. The greatest drawback to the enterprise is the comparatively small amount of gravel that may be raised with the crude means at hand.

However, in some spots as high as \$20 per day has been averaged for a week at a stretch. In many places where the prospects are most flattering, the formation of the river bed renders impossible the lifting of gravel in paying quantities. Little, if any, difficulty would be experienced with a dredger such as is used in the bay. The running expenses of the enterprise are nothing at all, the fuel for the engine being driftwood picked up along the beaches. So, if two men average from \$10 to \$20 per day, they consider themselves making big wages, with the possibility always in view of "striking it rich."

The Diestlehorst brothers began operations last fall, and the success they met with so encouraged them that one of the brothers came to San Francisco and bought a new engine and some necessary machinery with which to better prosecute the work this season. During the high water of the past winter the boat broke loose from its moorings and was carried several miles down stream, and it is now wisely proposed to prospect the river bed all the way back. It is possible that some wonderfully rich spots may be encountered, and if such happens to be the case it is probable that next year will witness the interesting spectacle of a fleet of gravel dredgers on the upper Sacramento.

IN one spot, about three-quarters of a mile east of Redding, a couple of negroes averaged from \$18 to \$20 per week all of last summer scooping for gold. They would wade out waist deep in the water, sink a bucket, and taking a long breath, settle under the water and fill the bucket with gravel. This was hard work and unhealthful, but it paid better than whitewashing or yard-cleaning in town. The negroes paid \$2 a month each for the privilege.—Bulletin.

Mineral Wealth of Amador County.

THERE is no questioning the fact that a new era of prosperity is about to dawn upon the mining industry of California. Amador county, situated as it is, on the very heart of the mother lode, ought to reap considerable benefit from the impetus that will to a certainty be given to the business of mining in the near future. There are miles upon miles of the mother lode within Amador's borders that have never been touched. Besides this there are immense deposits of ore on both sides—east and west—of the mother lode and running nearly parallel that where opened up and prospected, have proven fully as rich in the precious metal as the original vein, and there are cross ledges without number with good surface indications that the pick of the miner has never penetrated. It seems as though some "hoodoo" had taken possession of the mining energy of the people except in a few limited localities. The gravel deposits in the county cover nearly two-thirds of its entire area, and competent judges believe that if properly prospected and worked no richer mines of this character could be shown in the State. For more than 20 years past this branch of the mining industry has been almost utterly neglected; in fact from the start it seems never to have assumed any great importance in the mineral output of this county. The quartz interest has always seemed to overshadow every other mining enterprise. The *Record* is inclined to believe that one cause of the indifference of her people to Amador county's great mineral wealth lies in the fact that the most of them are farmers and stock raisers, owning their own land, and who, as a class, know nothing, and care less, about the millions of treasure that lie hidden under the surface of their broad acres, only waiting for the brawn and muscle of the hardy prospector to penetrate the mysterious depths that lie beneath the upper crust of hill and canyon and lay bare this golden storehouse of natural wealth ready at hand to enrich our people.—Amador Record.

Testing Ores for Working Processes.

TO THE EDITOR:—There is a general and justifiable distrust of experiments on a very small scale designed to test the efficiency of any given process, old or new, for the treatment of ores, and we often hear such a remark as, "Oh, it's all very well in the laboratory, but the question is, will it work in practice?" I say this feeling is justified, because it is historical that many failures have resulted from placing dependence on laboratory tests of processes which failed to yield similar results on a working scale.

Many years ago I heard of a wonderful smelting process by which pure silver was obtained in a single operation from an ore containing from 20 to 30 per cent of copper, a large proportion of lead, and a considerable quantity of antimony. I rode 100 miles on horseback, mainly to see this marvel, and it was a fact! The process was secret (?); but I was admitted to the works, saw the product, touched my tongue with a piece of the slag, *not, however, until it was cold*, and, presto! the secret existed no longer for me. The ore was smelted in a reverberatory furnace, and the, or a chief, flux was *nitre*. The enthusiastic inventor, who, by the way, was a *doctor*, was quite honest in the matter; he spent several thousand dollars of his own money, as well as other people's, on the venture, and he did what he said he would, in one sense, but it did not *pay*. If the worthy doctor had counted the cost, and the difficulty of doing continuously in a reverberatory furnace that which worked so nicely in a French crucible once or twice used, he would have known that it would not pay.

This is not the only instance in which the fascinating properties of nitre have captivated the fancy of would-be inventors. One gentleman, a metallurgist (?) this time, had the *scintillating* idea of using nitre to effect the rapid oxidation of auriferous sulphurets in the furnace. While he was experimenting, with great effusion and some success, a waggish friend suggested adding *sawdust* to the mixture; the next report was, "G—d—m it, it all went up the chimney." This result was not surprising to those who happened to know the composition of *gun powder*.

A recent instance of the failure of a metallurgical enterprise, based on laboratory experiments, was that of a young man who wished to work tailings by the cyanide process. Taking a pound of the material and shaking it in a bottle with cyanide solution, he found that the gold dissolved to a very high percentage. He then put up some vats and attempted to treat the tailings by percolation without agitation; the result was, that although the gold dissolved he could not get the solution out of the mud, even by the aid of a pump. Again, a gentleman undertook to test some silver ore by pan process, on a laboratory scale, in a common iron mortar. The same ore was being worked in a mill with fair results, being ground in the pans with bluestone and salt for several hours before adding quicksilver. The gentleman wished to imitate the mill operation exactly and, not being a practical metallurgist, thought he did so by taking a couple of ounces of the ore, grinding it for *two hours* with a similar proportion of salt and bluestone to that used in the mill, in a clean iron mortar, then adding quicksilver, and working without grinding for several hours more. The result was, not a trace of silver recovered.

I have found that ore which could not be successfully roasted in a Bruckner furnace, on account of haling, could be roasted well and easily in a roasting dish in the muffle. Iron pyrites can be perfectly roasted in the course of a few minutes before the blowpipe, yet an ordinary furnace requires from twelve to twenty-four hours to effect a similar result. The electrolytical decomposition of ores and recovery of their metals has been successfully accomplished many times on a small scale, and has failed many times when tried as a practical working process.

Instances might be multiplied almost *ad infinitum*, and this constitutes the justification of the prejudice against small tests in the minds of practical men of business, many of whom, nevertheless, continue to be led astray by the dreams of impractical experimenters, to say nothing of the schemes of rascally charlatans who know only too well that their projects must result in disaster to all concerned, themselves alone excepted, and who, together with the ignorant, self-lauding, "practical man, sir," make capital of the failures of honest, perhaps also scientific, enthusiasts who are lead away by *truths* which, however, must be co-ordinated with other truths in order to be applied successfully to practical purposes.

In order that a small test may be absolutely reliable as to results on the large scale, it is indispensable that all *essential* conditions shall be such as can be absolutely the same in the large as in the small operation. This applies to mechanical as well as to chemical and other conditions, not omitting the pecuniary feature, for metallurgy is an economic art, and it matters not how well a process may perform its function, if results cost more than they come to, or if a less perfect process yields larger profits without wasting the mine, the perfect process is of no practical use. I say without wasting the mine because it is notorious that valuable mines have been wasted to a great extent by the adoption of inferior methods in treating the ores, simply because those methods yielded larger immediate profits to the individual owners, a system which may suit them, as they cannot live forever, but should be discouraged by the State which will live when the greedy squanderers of *her* treasures shall be dead and forgotten.

But it is not always, I may say with reference to metallurgy not often, possible to make a very small experiment in which even *essential* conditions shall be precisely such as must necessarily obtain in the large way. Chemical reactions, *per se*, work alike in the large and in the small ways, and in the same time. I know this will be disputed, but I think the facts on which objections may be based are due to differences, sometimes unavoidable, in physical conditions such as contact of surfaces, pressure, exposure to air, conduction of heat, etc.; but I think that, for our present purpose at least, the statement may be admitted. If a pound of beans can be cooked by boiling for three hours, a hun-

dred pounds can be cooked in the same way in the same three hours; but when we come to the question of heating the water in the pot to boiling, we shall find a difference in the time required, unless we have equal proportional heating surfaces, and a pot of the same material and thickness. This illustrates, in part, what I mean by equality of essential conditions. But we shall also find that the consumption of fuel will be less in proportion for the larger quantity than for the smaller, unless we assume that the hundred pounds shall be cooked in as many separate pots over an equal number of separate fires, which would be simply multiplying our operation instead of enlarging it. And this is a point which must be considered in metallurgical tests, or, perhaps I should say, it need not be considered, because it is impossible to work on a small scale, where artificial heat is required, with as much economy of heat as on the large scale, while, on the other hand, we can attain our results, in that respect, more quickly in the first than in the last case.

The reason why a charge of pyrites in a furnace requires many hours to roast it, while a grain or two of the same ore requires but a few minutes before the blowpipe is, primarily, a mechanical one; the relatively deep bed of ore in the furnace is less exposed to the action of heated air. A chemical difference supervenes, because the effects of heat without exposure to air are different, and a large part of the ore in the furnace is excluded from air at any given moment. A similar explanation may be given of the fact that an ore which can be well roasted in the muffle, or in a reverberatory furnace, may ball in a Bruckner cylinder. The action of the Stetefeldt furnace illustrates this matter, and, for such ores as can be roasted by the brief exposure possible in it, is a most excellent device. But Stetefeldt roasting cannot be done on a very small scale; it can be approximately imitated in the muffle by "instantaneous roasting," so called; yet the chemical conditions of muffle roasting differ from those in any other furnace, and I think small roastings can never afford a perfect criterion of results in the large way.

Concentration, with or without previous sizing, can be done by hand as well perhaps as, hardly better than, by machinery; but the condition of the ore powder, as produced by various crushing appliances, is an important factor which must be carefully attended to.

Leaching and lixiviation, as often done in the laboratory, give imperfect indications of what may be done in the mill, especially as to rate of filtration and time required, but also as to results depending on washing and draining. This work should be done better than it usually is when the customer's object is to know what to do and how to do it. *The nature of the filter, the condition of the ore, and the depth of the column should be the same as they will be in the mill; the area is of little or no importance. The effect of "suction" should be observed as to its effect in accelerating the work, and especially as to extracting a higher percentage of the metal by the more perfect washing and draining, also as to the reduction in quantity of washings.* In tests of the cyanide process, attention should be given to the consumption of cyanide, and the means, manner and cost of reducing it if excessive; this may involve some analytical work, but customers should not grudge the cost; it is better to spend a few hundreds in the laboratory than thousands in the mill for information.

Chlorination in vats can be represented very well in the laboratory, that is as to results, not as to consumption of chemicals which will be much greater, proportionally, than in actual work; of course the condition of the ore must be the same in each. Operations which are performed in revolving barrels, such as chlorination, amalgamation, and agitation with cyanide solution, can be imitated or tested very well in bottles, both as to time, consumption of material and results; but, in recommending machinery, regard must be paid to the nature of the liquids, etc., as to their action on the material of the barrels. Iron or wood may be used for the cyanide process, but iron would not do at all for chlorination, that is, on the inside of the vessel.

Pan amalgamation cannot be perfectly imitated in the laboratory. The idea that an iron mortar and pestle form the *simulacrum* of a modern amalgamating pan is an error. If the pulp is not deep in the mortar, the grinding action is excessive; if a larger quantity be used, the mixing and agitation is imperfect. The mortar is especially defective for testing silver ores by the so-called Washoe process in which bluestone and salt must be used, because the iron surface in contact with the pulp is much larger in proportion to the mass of pulp than in the mill, hence the cupric chloride is decomposed much sooner. In this regard, as in many others in metallurgy, a knowledge of the mathematical law of proportional surface and mass is useful. Moreover, a clean mortar is generally used, and the mercury is usually reserved for some time. Even when the mercury is added at once with the ore, the result is not the same as that in a pan which, from previous use, is coated with amalgam. The best that can be done is to prepare the mortar in advance by putting into it some solution of bluestone and some quicksilver and causing the iron surface of the mortar and pestle to become coated with quicksilver as far up as the pulp will extend, the liquid being then removed and the ore added, also quicksilver and the desired quantity of water, bluestone and salt. The whole should be warmed and the pulp stirred, but not ground; it should be already ground as finely as may be considered desirable before making the test. Even thus more bluestone must be used, in proportion, than will be needed in the mill.

But this test can be better made in a bottle, by shaking, iron scraps being added in such quantity as to expose about the same proportional surface as will be the case in the pan. In this way, the pulp being made with hot water, and temperature maintained by occasionally putting the bottle into hot water, and the iron being previously coated with mercury by the means described, a fair imitation of pan-work may be got, both as to time required, as to proportion of chemicals, and as to results. I think, however, that the best way is to treat the previously powdered ore in a porcelain or enameled dish, over a coal-oil stove or

gas flame, with the requisite chemicals and quicksilver, and some scraps of iron which should be first amalgamated as above described, stirring the whole frequently by means of a glass rod or a stick. The iron surface should be approximately, in proportion to the weight of ore, similar to that of an ordinary mill pan.

A model pan, in all respects similar to the mill pan, but holding only a few pounds of ore, is sometimes used for these tests; it is, to a less extent, open to the same objections as the mortar; the extent of iron surface is too great for the quantity of pulp; that is, it is much greater than in a large pan of similar form. In all cases where a test is made on a small working scale, that is in pans, etc., which have been used before, the assay of a true sample of the tailings is a more reliable criterion of the work done than the apparent proceeds, because it is scarcely possible to clean pans or copper plates, etc., so that a subsequent operation may not be more or less vitiated, especially when poor ores follow rich ones.

It is in those cases in which a perfect *simulacrum*, on a small scale, of the proposed operation on a large scale cannot be obtained, and such, as I have said, are a majority, that the judgment and general knowledge of the experimenter or inventor are put to a severe test. As to proportions of chemicals, which should be strictly observed, it is generally, though not invariably, possible to make the necessary determination in the small way. In this respect, in many cases, I will undertake to do with a thousand tons that which I do with a thousand grains of ore.

But inventors of new processes have to consider a number of matters. A process requires an apparatus, and material which is available on a small scale, such as porcelain, glass, gold, silver and platinum, cannot, in many cases, be employed in working, either on account of cost, fragility, or the impossibility of manufacturing in the requisite sizes, or because the physical properties of a substance which answers for small machinery fail on a larger scale; for a substance does not become harder with increase of mass, and the tensile strength, resistance to flexure, etc., increase in a smaller ratio than the weight. An iron beam may support a great weight, in addition to its own, but, if the size should be increased indefinitely, a point would be reached at which it would no longer support itself. Machinery which works well and endures long when small, may work badly, or wear rapidly, when large. All of these matters must be carefully considered by the man who would successfully launch a new invention, whether in metallurgy or in another branch of industry, and it is precisely the neglect or inability to justly estimate their value that blasts the hopes of many honest inventors, and causes pecuniary loss to those who invest money in their schemes. C. H. A.

A Smelter for Los Angeles.

TO THE EDITOR:—With the prospects of an active smelter in the corporate limits of this city at an early date and a generally increased interest in mining in this section it looks as if we are indeed close to a genuine mining boom.

The smelter will probably be ready to buy ores in thirty, and for smelting in sixty days. Then southern California will surprise the world with the quantity of good smelting and other classes of ores it can produce. Several good properties are now being developed and ore taken out for shipment to the new smelter.

The question is often asked, "Is there anything in it?" etc., to which I will say that the foundation is being laid and several carloads of machinery have arrived. The chief promoter, Dr. Endlich, seems to be a polished gentleman of fine education and ability, having had much experience in the old country and in this. For years he was in the Smithsonian at Washington and is the author of an elaborate and excellent work in mineralogy.

Los Angeles is also liable to become quite a center for interest in the new cyanide process. We have with us now two gentlemen from Tombstone, W. H. and L. E. Aubury, who are among the few who have successfully worked out the practical details of the process. They have thus been treating ores in Tombstone for the past year and making eight and ten dollar silver ore pay. They have also made some valuable modifications of the process, in recognition of which the Denver Company has granted them special privileges in working ores. They are now arranging to erect large plants at several mines in southern California, and putting up a small one here in the city to demonstrate the practicability of the process on various ores. Like the amalgamation, the Russell, or any other process, it is, of course, applicable only to a certain class of ores, though to a greater extent than is generally supposed. Each case has to be determined by a practical working test.

Sampling works are also in prospect of being erected here soon. E. M. WADE.

Mines at Elk City, Idaho.

TO THE EDITOR:—Since my letter describing this camp appeared in the MINING AND SCIENTIFIC PRESS (Feb. 18th), a great many mining men have written me, asking information with regard to transportation, freight rates, water power, quality of ore and what hases are associated with the precious metals. I have answered all of them so far, but the mining season is here now, and it will be very inconvenient for me to answer so many letters. So with your permission, Mr. Editor, I will try and give all whom it may concern a short description of the camp, its resources and transportation facilities.

At present this district is connected with the outside world by pack trail only, but the Legislature of the State of Idaho at its last session, appropriated \$130,000 to build roads and open up the rich mining sections that are known to exist in the fastness of the mountains of this young State. A part of this money will be spent this summer in the construction of a good wagon road to Elk City, which will make 100 miles by wagon or stage to

Lewiston, the head of navigation on Snake river, and 115 miles to Union Town, on the Northern Pacific railroad.

Freight from Portland, Oregon, to Elk City, at present, is five and one-half cents per pound, but with the wagon road any common freight can be delivered here for at least four and one-half cents per pound.

The water power of the camp is practically unlimited, and very convenient, as the different groups of mines are cut by large bodies of water that can be controlled by dams and flumes, thus insuring cheap power sufficient to run almost any size milling and reduction plants. The altitude of most all the mines is less than 4,500 feet; the winters are mild, the thermometer seldom going below zero, consequently little time will be lost on account of cold weather.

With regard to timber, "the woods are built of it." The hills are covered with a very thick growth of black and yellow pine, red and white fir, tamarack and cedar.

The auriferous ore of the district is common iron pyrites. There is practically no other bases but the iron and sulphur. Occasionally a little arsenic or a trace of copper is found. There is no lead, bismuth, plumbago, or antimony; at least the assayers of the camp report none.

There are three or four lodes in the camp that run high in silver and carry considerable more bases than the gold ledge, but there being only a few of these claims they do not effect the general description of the camp.

M. L. MURRAY.

Elk City, Idaho, May 6, 1893.

The Texas Consolidated.

Shasta County's Big Mine in Old Diggings District.

Mr. L. S. Barnes, the editor of the *Shasta Democrat*, has been out to Old Diggings district visiting the Texas Consolidated mine, the property of R. G. Hart, and superintended by R. G. Hart, Jr. Mr. Barnes' description of the property is as follows:

The first thing of interest we inspected was the milling plant, erected on a solid rock foundation on the east bank of the Sacramento river, about a mile from the principal ore dump on the mine. The plant consists of twenty 850-pound stamps, eight Triumph concentrators, a Blake rock-breaker, four automatic ore-feeders, a Morris concentrating table, a large water pump, and a 50-horse power engine and hoiler, which furnishes the power that operates the whole plant, and enough power in reserve to operate 20 more stamps. The whole plant is a very substantial structure, covering a ground space of 150x60 feet. Forty tons every 24 hours is the capacity of the mill, using a 30-mesh screen in the batteries. The water that supplies the mill is pumped from the river into a large reservoir above the mill during the summer months, but during the wet season water is piped from ravines. The capacity of the Blake rock-breaker is 100 tons every 24 hours. The ore is delivered to the ore bins above the stamps by self-dumping buckets suspended to an endless steel wire cable. This portion of the plant was put up in November and December, 1891, and is known among mining men as the Hallidie wire tramway. The cable makes a circuit of about two miles, and at intervals of every 160 feet a self-dumping bucket is hung. As these buckets pass around the drum at the station at the mine dump two men fill them with ore, and a bucket of ore is dumped into the ore bin above the rock-breaker at the mill every 40 seconds. The capacity of the tramway is 50 tons of ore delivered at the mill every nine hours. It requires only two-horse power and two men to operate it.

From the rock-breaker the ore drops into bins that feed the automatic feeders that supply the stamps. Each battery of five stamps discharges through a 30 mesh slot screen onto amalgamating plates ten feet long and as wide as the batteries. The pulp from the batteries passes over these plates, is collected in troughs and distributed equally to eight Triumph concentrators, which save the heaviest sulphurets. But the output of the stamps is not done with yet. From the concentrators the slimes and fine concentrates pass on to a Morris concentrating table, which has 22 parallel runs, each about 16 inches wide. In these runs No. 2 canvas is laid, which collects and retains a large per cent of the slimes and light sulphurets that escaped the Triumph concentrators. Every one and a half hours these canvas strips are freed from gangue by the application of clear water, then the slimes and fine concentrates that have lodged on the canvas are hosed off into a long trough. Here the slimes and fine concentrates settle. This is the end of the process of saving the precious metals that the stamps free from the virgin rock. In connection with this plant is a complete laboratory and assay office. The fact that the tallings assay but a trace proves that but little value is lost in milling.

The mine is now known as the Texas Consolidated Mines, and consists of six patented and two unpatented claims, covering 7500 linear feet of ground, and a portion of it the width of two chains. The claims run from the base of the mountain on the west side to the east side of the mountain. There are three well defined parallel veins inside the patented ground. On the center vein on the claim originally known as the Texas & Georgia, most of the development work and exploring of ore bodies has been prosecuted. There are four main tunnels penetrating the ore zone, all run on the vein, and tunnel No. 5 is now in about 400 feet.

Tunnel No. 1 is in about 280 feet. At the end of this tunnel the ore body is about 14 feet wide at a depth of 160 feet from the surface. But very little of the ore above this tunnel has been stoped out.

Tunnel No. 2, which makes a level 96 feet lower than that of No. 1, is in 375 feet. About half the ore between these two levels is in reserve, and the vein for the full length of the tunnel averages about six feet, all milling ore.

Tunnel No. 3 is in 1240 feet. The pay chute is over 500 feet long in this tunnel, and the greatest vertical depth from the surface is 666 feet. The last 600 feet of this

tunnel is a drift that was driven to cut the east vein, and on the second of this month this drift encountered the vein at a depth of 660 feet. The vein at this point is 5½ feet wide with a 30 degree pitch to the east, or into the mountain, and the ore at this exposure is all high grade. We consider this the most important development in the history of this mine. The stoping ground in the chute between levels two and three is practically all reserved, and in places the ore bodies along the chute swell out to immense breadths.

Tunnel No. 4 is in about 900 feet, and about 580 feet of which is pay chute. In places the ore bodies swell out from six to sixteen feet wide from wall to wall, and we approximate the average width of the vein the full length of this level at about eight feet. At a point about 550 feet from the mouth of this tunnel a winze 80 feet deep is sunk on the vein. At the bottom of this winze the vein is 12 feet wide and 880 feet perpendicular from the surface, and all high grade ore. This is the deepest penetration in the mine or ore zone. For 500 feet along this ore zone between tunnels three and four, and an average of 40 feet high, the ore has been stoped out and milled, but the remainder of the ore between these two tunnels remains as a reserve in place.

Tunnel 5 has been started and is now being pushed ahead. This will give an approximate depth on the center vein of about 900 feet, and through this tunnel all the big ore reserve will pass to the mill.

To give the reader a fair illustration of the extensive ore bodies in this mine, it is only necessary to state that Foreman Ed. Hume has only eight men at work breaking ore to supply a 20 stamp mill. Another thing about the mine is the absence of culled ore around the dumps. Everything in the shape of ore goes through the mill.

The west vein is being developed by a crosscut from tunnel 3 on the center vein. The drift on this vein from the intersection of the crosscut is 90 feet and the vein averages about six feet. Some of the ore on this vein is stoped out clear to the surface, and some assorted ore has been shipped from this vein.

We are free to confess that the dimensions of the ore zone we saw in this mine was a complete surprise to us. We were not prepared to see anything like it. It is a big mine, and one that will make a record for Shasta county.

We must not forget to pay our respects to Foreman Ed. Hume, who piloted us through the many levels, stopes, crosscuts and drifts. The system of development here stamps Mr. Hume as an expert miner. Very little dead work is to be seen in the whole mine. Mr. Hume is a genial gentleman, justly proud of his achievements in this great mine, and is appreciated by the men under him.

Mr. R. G. Hart, Jr. is not only superintendent and general manager of this big property, but is also president of the Cleveland Consolidated mines, better known as the Bullychoop group of mines, on Bullychoop divide, between Shasta and Trinity counties. The mines are situated just over the line in Trinity county. Last summer he did considerable development work on this property and almost completed a new milling plant when the winter snows compelled a cessation of work. He will resume operations on this big property before the first of next month.

Old Diggings camp presents quite a thrifty scene. Besides the Texas Consolidated there is the Walker mine, superintended by H. D. Rippetto; the Crystal, Mammoth, the Reid group, and several other claims of lesser importance—the whole camp sustaining a population of about 250 or 300 people.

This trip to Old Diggings impressed us of the importance of water power, and that can be had. There is an old water right with an old unused ditch running up to the Pitt river to a point near its confluence with the Sacramento. This ditch could be enlarged so as to bring 1000 miners' inches of water through this camp at an altitude to give several hundred feet power. Enough power could be generated to drive all the machinery, either by water or electricity, this camp will ever need, and the water after this use could then be conveyed on toward Redding. A competent engineer has estimated that an expenditure of \$20,000 would bring that volume of water through this camp at an elevation of several hundred feet above any mill site in the camp. This is an enterprise that surely ought to attract capital if properly presented. There is an immediate demand for water power for the mines, and a large prospective demand for irrigation after the water would pass the divide between Quartz Hill and Old Diggings.

Diamond Digging.

I have just spent a few days among the river diamond diggers near Hebron on the Vaal, says a writer in the *Jewelers' Circular*. The work there is carried on by individual diggers, each man leasing his claim and working it himself with the aid of a few native laborers. They are a motley crowd, these diggers, and representatives of almost every nationality. It is a hard and precarious existence. Diamonds are few and far between, but when found, nevertheless, they are generally of first-class quality and realize high prices.

The diggers are mostly men of very small means. Their tools and washing gear are about all they have, and they consequently live very poorly. Meal of rough quality is often the only food that passes their lips from one month's end to another. They usually get on credit from some storekeeper, who furnishes them with the bare necessities of life on the chances of their finds. Most of the diggers, of course, have a find some time or other, though there are strange instances of ill-luck following the quest for diamonds year after year.

I had a conversation with one old man who had been at this sort of work for 19 years, and I am afraid to say how long it is since he had a turn of luck. He has lived nearly all this time on meal, and there he was toiling away at about the hardest work man can undertake, yet seemed

willing to go on to the end. This labor, however, though heavy, has a wonderful fascination for those who once take to it. A very fine stone had been found a few days before my arrival. It was valued at between \$2500 and \$4000. Towards the end of last month two brothers had a marvelous run of luck. They found stones to the value of over \$20,000 in a very short space of time.

Geology of Building Stones.

Of interesting sciences, there are none more so than geology—the study of the earth. The material substances about us, the handwriting of Dame Nature, is by the power human reasoning made to reveal the secrets of the past. With this mighty weapon, knowledge is well armed in the constant conflict with tradition, superstition and falsehood.

But there is to be found in this great historical storehouse one chapter that reaches its usefulness out to us in our everyday life, and adds an interest to what may at first seem to be things of the commonplace.

It will say "stones for building." To the layman this conveys little more than the idea of a block of hard material that has proved a very useful thing with which to construct a habitation. To the architect it conveys a feeling of pleasure, a friend of great possibilities; while to the mason it is the staff, the rib of his existence. But to the geologist, the words are of significance—the rib of the world. Of these, which is the more exalted? Let us listen to the geologist. With pleasure, if he will drop the isms and asms of the technical.

Order is one of the first and best laws of nature. The geologists are orderly, or nothing. Thus they began a classification in the earliest stages of their investigation of the earth's rocks. In the first arrangement, such rocks as were supposed to have been original in their formation were called primitive, and such as were composed by the disintegration of others were called secondary. In the primitive rocks there are never found the remains of organic substances, as shells or plants, from which fact we infer that they were formed prior to the existence of life in any form. On the other hand, the secondary class often contained fossils of all kinds, and portions of what must at one time have been primitive rocks. But these early scientists were entirely too simple in their nomenclature for the modern schools. Since that time, the latter have been busily engaged in inventing new names, and championing them abroad after their invention.

For the use of the layman, however, an easy classification of rocks is as follows: 1, primary; 2, transition or intermediate; 3, secondary, (a) lower secondary series, (b) upper secondary series; 4, tertiary; 5, basaltic and volcanic; 6, diluvial and alluvial.

Before taking these up, I should not forget to mention what a rock is.

"Oh, everybody knows what a rock is."

All right then, what is it?

"A rock is a—a—rock."

I thought so, too. A rock is an aggregation of minerals, occupying a definite position in the earth's structure. It could be one mineral as well as more than one, out as a matter of fact the pure mineral is never found.

The primary rocks are the ground work of the globe; they are the ribs of the world. They rise into lofty mountains, and are the floor beneath which we have never penetrated. One of the most notable of these rocks is granite; I might better say granites, for the number of kinds is legion. However, the differences are very small, indeed, being more in what are really impurities than anything else. The usual three minerals are found in them all—quartz, feldspar and mica. Quartz is a white, glassy substance that breaks in an irregular manner. You have often broken the smooth, white pebble that so often abounds wherever there is running water? Ten chances to one that pebble is quartz. It is the mica in granite that sparkles so. The bits are small sheets or leaves, very small indeed, but still abundant enough to give the greenish tint so often noticed. Large pieces of this same mica is called isinglass, and is certainly familiar.

Other primary rocks are gneiss (pronounced like the word nice), mica-slate, clay-slate, primitive limestone, porphyry and syenite. They are all, as a rule, crystalline in their structure, and never contain remains of organized substances or portions of other stones. By organized substances, we mean living things, as plants and animals.

Gneiss and mica-slate are composed of the same materials or minerals as the granites, only arranged somewhat differently. The grains are, as a rule, very much smaller than in the granite. In gneiss, the quartz and feldspar are very closely aggregated, while the mica is arranged in scales between strata of the same. Hence it is that gneiss is really a stratified rock, and if a section or break be made at right angles to the strata, it will present a striped appearance, for the quartz and the feldspar are nearly white and the mica a narrow band of green. Often the mica is a deep black.

Mica-slate is composed principally of quartz and mica and a very small portion of feldspar. The latter is sometimes all but absent. The quartz is commonly in the form of fine sand, and the mica in flakes. The latter predominates and sometimes seems to be the entire composition of the rock. Mica-slate differs from gneiss in having a small portion of feldspar; and more in the positive stratification which is so marked that it is easily separated by wedges into plates or layers. An example of the latter quality is found in the common flagstone.

These three stones—granite, gneiss and mica-slate—form what is known as the granite group, and together they form the major portion of the earth's crust. The gneiss is intermediate between granite and mica-slate in its structure, and is often found between these rocks, lying over the former and under the latter. Sometimes the transition is so gradual as to be hardly perceptible, the granite growing to a stratified gneiss and the latter as slowly into fissile mica-slate.—Edward C. Weaver, in *Stone*.

Mechanical Progress.

Advanced Speed Records.

A dispatch from Buffalo, N. Y., dated May 9th, says: The New York Central Railroad's Empire State Express broke all railroading records this afternoon in a run from Rochester to Buffalo, attaining a speed of 102½ miles an hour. The train was drawn by the new Columbian engine, No. 999, which will be sent to the World's Fair. Miles were made in from 42 to 50 seconds right along until Corfu was reached. The distance from Corfu to Crittenden, four miles, was made in 3½ minutes, and the two miles between Wende and Looneyville were rolled off in 1½ minutes. The track from Looneyville to Forks station is as solid as a rock and well adapted to record breaking. The distance is nine miles and it was run in 6 minutes and 58 seconds. Just before the Forks was reached a mile was made in 35 seconds, timed by a stop watch. The 69 miles from Rochester to Buffalo were made in 68 minutes.

On May 11th, another dispatch says: The great Empire State Express engine 999 has broken her record of 102 miles an hour, which she made last Tuesday. The test was made between the Rochester depot and Buffalo yesterday. After Batavia was reached Engineer Hogan let her out, and the engine, hauling the great Empire Express train, was going at the rate of a mile in 35 seconds at Crittenden. Beyond Crittenden the world's record of a mile in 32 seconds was made. This is equivalent to 112½ miles an hour. This tremendous speed was kept up until Forks station was reached. There was no unusual swinging or jolting.

Another great record is that of the new steamer Campania, thus announced in dispatches from Queenstown dated May 12th: The new Cunard steamer Campania arrived this morning from New York, beating the record of the eastward passage, doing it in 5 days, 17 hours and 42 minutes. There is great jubilation over the victory.

It was a race between the Campania and the Paris of the American line. The Paris passed Sandy Hook lights at 10:58 A. M. Saturday, May 6th; the Campania at 11:13. The latter gained steadily on her rival and passed her 109 miles east of Sandy Hook. From that time on the Campania did not sight the Paris. The best previous eastward time was that of the American-liner New York, last August—5 days, 19 hours and 57 minutes.

The first trip of the Cunard Company's first boat, the Britannia, was made in 1840 and occupied 14 days and 8 hours in its run to Boston. This boat had a capacity for only 115 cabin passengers, while the Campania, its latest successor, can carry 600 first class, 400 second class and from 700 to 1000 third class. On her trial trip on the Clyde she attained a speed of 23½ knots, equal to 27 miles an hour, a record unsurpassed by any steamship, and on her maiden trip she made the distance from Queenstown to New York in 6 days and 4½ hours. This for a maiden trip was a remarkable record and fully bore out the expectations of both her builders and owners.

The Campania has 12 main boilers and two auxiliary boilers. The 12 main boilers are double ended, 18 feet in diameter and 17 feet long, each having eight corrugated furnaces, four at each end, with a combustion chamber in common to each pair of furnaces. Of the auxiliary boilers, one is 18 feet in diameter by 11 feet long, with four furnaces, and the other 10 feet in diameter by 10 feet long, with two furnaces. These two auxiliary boilers are intended primarily to furnish steam to operate various appliances about the ship, but they are so arranged as to be used in connection with the regular battery for driving the ship when required. The main boilers are the largest yet made for the pressure required—165 pounds. The plates were supplied by the Steel Company of Scotland and are 17-32 inches in thickness, some of them being 20 feet long by 7 wide.

At Liverpool, on May 12th, the Campania landed her passengers at 10 o'clock, and thus beat all previous records. She steamed from Queenstown to Liverpool in 10 hours and 3 minutes, or at the rate of 22.48 knots an hour. The officers of the Campania cannot say enough in praise of her engines and sea-going qualities. The Cunard Company is receiving numerous telegrams of congratulation.

LIFE-SAVING KITES, invented by Prof. J. W. Davis, were successfully tested near Newport, R. I., on April 24th. A kite was sent in a 25-mile breeze from Breton's Reef lightship to the shore, 1½ miles away, carrying with it a life-line. One mile of line ran

out in 41 minutes. The two kites used were in the shape of six-pointed stars, seven feet in diameter, and covered with oiled duck. The first kite was attached to a float at the end of the life-line and the other half a mile back of that. The life-line was manilla, one-fourth inch in diameter, rated to bear a strain of 780 pounds. This line terminated in a loop, and about 20 feet back was slung a solid wooden 32 pound buoy.

Cheap Clocks and Watches.

A correspondent of the *American Machinist* says: At the Waterbury Clock Company's works, where they are at present turning out about 1500 clocks per day, there is much to be seen that is of interest, especially in the way of tool work, which is very finely done. In one room 45 automatic screw machines are at work, making not only the screws but many other of the small parts of clock movements which in the old days were made on hand lathes of special design. Some of the work must, of course, still be done in this way, the tools used, however, not being the usual hand tools, but tools set in a square bar of steel, the ends of which are turned cylindrical for some distance and rest in supports upon which the bar slides along to take the cut, the tool in action being supported upon a rest which is placed near the work. The various tools are held in the bar by set-screws, and are adjusted in it to give the proper diameters of the various parts of the piece operated upon, and the bar turned from one tool to another does the work very rapidly.

An interesting line of work is being developed here at present which is the outgrowth of the fact that the company found that one of their smaller sized clocks was being carried by many people as a watch. It was, of course, rather large for this purpose, but the fact that it was so used led to its being modified, particularly in the way of reduction of thickness. The result of this is that the time-pieces are now being made so that they can be used either as clocks or as watches, and the system by which they are made admits of their being sold at retail at \$1.50. They are neat in appearance—rather large to be carried in the pocket of a full dress suit, it is true, but very acceptable for many uses, and I can, within reasonable limits, give no better idea of the efficiency of the processes by which they are made than to state, as I have done, the retail price, which includes, of course, about three profits above the actual cost of manufacture.

The name of the Waterbury watch is associated in the minds of many people with extreme cheapness and a quality in keeping with the price. The factory and its equipment, however, are mechanically of a very high grade. The original factory was contracted for from the foundation of the building to its complete equipment in working order by the American Watch Tool Company, of Waltham, and as might be expected, the contract was carried out in the best possible manner; the shop, its equipment of tools, the arrangement of them and of the tool rooms, store rooms, power plant, etc., being very admirable, as is also the cleanliness, order and evidence of good management that prevails the place. The original Waterbury watch, however, which the boys in the shop used to wind up by holding the stem against a running belt, has been abandoned and various higher grade watches are now made which are cased in any desired manner, the company claiming the distinction of now producing the thinnest full-sized watch made. In one moderate sized room of this factory are small automatic and other machines to the value of about \$125,000.

SIXTEEN MINUTES' SHOES.—When one looks back a hundred years and thinks of the days of tedious traveling it took to make the journey from Boston to New York, and then calls to mind the magnificent new compound locomotives which are capable of drawing a train of cars at the rate of between 75 and 100 miles per hour, he is struck by the wonderful progress which has been made in mechanical science during the current century. Yet, as great as has been the change in our modes of locomotion, it has been no greater than that which has occurred in other fields. For instance, it was but comparatively a few years ago when Henry Wilson, afterward Vice-President of the United States, was laboring at the shoe-bench, spending hours, and probably a day or more, as did all his fellow-workmen throughout the world, in making a single pair of shoes. Now machines for doing this work have been so highly developed that this week a pair of shoes was actually made in Lynn, from beginning to end, including the sewing on of the buttons and the packing of the pair in the box, in the almost incredibly short time of less than 16 minutes.

The compound locomotive and the 16-minutes' shoes are not exceptions, but only examples of what has been accomplished throughout the entire list of mechanical industries.—Manufacturers' Gazette.

Scientific Progress.

Iris Glass and Its Composition.

There are often seen on the market fancy articles of glassware, such as vases, bonbonniers, salvers, trays for visiting cards, paper weights, lamp shades, etc., the surface of the glass being so treated as to possess all the rainbow colors, changing one into the other in different lights, known as iris glass. The method by which this beautiful effect is attained is described in the *German Journal, Die Glashutte*, and is given below. It is done by the glassblowers at the furnace, in an apparatus which consists of a sheet-iron cylinder 20 inches long and 8 inches in diameter, standing vertically, having a similar cylinder riveted across the top, making a T-shaped muffle. In the lower cylinder is an opening into which an iron ladle can pass. The horizontal cylinder is provided with doors at either end, the one nearest the workman being so arranged that the blow pipes can be supported when the door is closed in a horizontal split running to its middle, the article to be treated being held inside. The whole apparatus is placed on the work bench, convenient to the glassblower. While the latter is re-heating his work for the last time in the furnace, the helper takes the long-handled iron ladle, which has been heated red hot, and shakes into it about a spoonful of the mixture given below, and places the bowl of the ladle quickly in the opening provided for it in the vertical cylinder. The mixture immediately gives off vapor, which rises to the horizontal cylinders, where, in the meanwhile, the blower has placed his work, supported by the blow pipe, and heated to an even red, turning it rapidly in the vapor. After a little while the object is covered with a changeable luster, is removed from the pipe and tempered in an ordinary oven as is other ware, and afterwards cut, engraved, painted or gilded, as desired.

The chemicals which make up the mixture that gives off the coloring vapors are the same as those used to give the brilliant hues to rockets, fireworks, etc. Strontium monoxide gives red; strontium nitrate, rose; barium monoxide gives blue; barium chromate, green; chloride of zinc, white. A flame-like luster will be given by either of the following receipts, the ingredients being carefully mixed on a plate: One part by weight powdered oxide of strontium, one part by weight powdered oxide of barium, two parts by weight powdered oxide of zinc; or one part by weight chromate of barium, two parts by weight oxide of zinc.

The Electrical Congress.

One of the most important features of the gathering of electrical people at the World's Fair this year will be the meetings of the Electrical Congress in connection with the exposition. This congress, it is anticipated, will be composed of representative scientists from every part of the world, and the work they have in hand will be of great interest and importance to the industry generally. Former gatherings of this description have awakened considerable interest, and some of them have been instrumental in bringing about advancements in the art and the determination of points of controversy. None of them, however, have had the excellent opportunity which is presented the congress which will assemble in Chicago this year. Upon the question of program Prof. Carhart says: "The committee having charge of this important congress has been alive to the interests involved and the responsibility of making the most of the opportunity in the interest both of the science and the applications of electricity. The occasion is a fitting one on which to settle in an official way the matter of electrical and magnetic units and nomenclature for years to come. With this in view, provision has been made for an official or legislative council, the members of which shall be appointed by the Governments which they represent. To this council shall be submitted all questions bearing upon the adoption of units and terms. After the legislative council has passed upon the questions coming before it, the units adopted will only need ratification by the several Governments represented to become truly and legally international." The official character of the congress, together with the standing of the men who will compose the body, will lend great weight to its decisions. The fact that the meetings will be held under the sanction of the Gov-

ernments represented will greatly influence the public in accepting its decisions. Marked contrast is shown between the congress of 1881 at Paris, that held three years later in Philadelphia, and those of more recent years with which we are all familiar. These proceedings, while interesting, instructive and valuable, did not attract the wide attention or receive the same consideration as those of the original congress at Paris. It is believed that the Chicago congress, by reason of its official character and the eminence of the men who will participate in its deliberations, will even out-shine the Paris assemblage of 1881. This is to be hoped, at least. The gentlemen in charge of the arrangements have availed themselves of the experience and advice of the leading electrical scientists of this country and Europe.—Western Electrician.

Diffused Light.

The London *Electrician* reprints an article from a Viennese gas journal, on indirect lighting, which gives some interesting results regarding diffused light. With ordinary lighting, six seats on one bench in a lecture room in the university had an illumination of 8.4, 12.7, 45.8, 74.9, 16.9 and 11.0 metre-candles, respectively (one metre candle is about equal to a foot-candle). Various mirrors and reflectors were then introduced below and above the lights, so that the illumination consisted entirely of diffused light. There was then no shadow and no reflection from the walls, the flames were out of sight and the objectionable heat from the lights did not radiate downward; the room seemed to be divided into two zones, the upper one bright and the lower one dark; the only defect was the comparative darkness of the lower part of the room. Measurement showed that with the same consumption of gas the illumination in the brightest place was 26.15 metre-candles with direct and 8.59 with indirect lighting, and that in the darkest place was 16.58 and 6.74, respectively; the average was 21.33 and 7.64, showing a loss of 64.2 per cent. The illumination was not sufficient in the second case, as it was found that nothing less than 10 metre-candles (or about one foot-candle) was sufficient. The walls of the room were then painted a pure white; the averages then were 24.01 and 9.11, or a loss of 62.5 per cent. A semi-transparent reflector of paper was then substituted; the averages were then 21.01 and 9.94, or a loss of 52.7 per cent; paper, however, is not a good material, as it discolors. Milk-glass was then tried, as it was, to some extent, both transparent and a good reflector; the room then looked much brighter; the averages then were 27.05 and 17.48, showing a great increase; the loss was thereby reduced to 35.6 per cent, and the worst-lit part of the room was found to be sufficiently illuminated; the lighting, however, was not so uniform with a semi-transparent reflector and the shadows were not entirely absent.

Explosion of a Storage Battery.

Mr. F. C. Bliss, of the Bliss Engineering Co., Washington, D. C., sends us an interesting account of an explosion of a storage battery which, fortunately, in this instance, had no serious results. Seven Julien cells being charged from a 110-volt circuit with 10 amperes, were disconnected while in circuit by disconnecting the wire joining the middle cell to the adjacent one, in order to put in another cell. At the instant of breaking connection there was a vivid flash followed by a loud explosion; the cell was completely wrecked and several persons standing near were thrown backward and deluged with acid. The heavy iron clamps which secured the top to the sides of the cell were forcibly broken and the iron handle thrown to the ceiling, breaking out a section of lath and plaster where it struck.

The explosion, of course, was due to the spark caused by breaking the circuit igniting the uncombined hydrogen and oxygen gases in the cell. A similar accident occurred in Pittsburg several years ago with serious results. In this case the cells were in a box closed with a lid, and the explosion occurred while an examination was being made by the aid of a candle, the flame of which ignited the gases that had accumulated before the lid was raised.

Other cases have been noted, and, as uncombined gases are always present near the end of a charge, due to the fact of the plates only taking up a portion of the gases released at that time, great care should be exercised in approaching a light or breaking a connection where the situation is such that the gases may have had an opportunity to accumulate. Closed cells such as are used with phonographs are particularly liable to this accident.—Electrical World.

Metallurgy and Ores.

SELBY
SMELTING and LEAD CO.,
 418 Montgomery St., San Francisco

GOLD AND SILVER REFINERY
And Assay Office.

Highest Prices Paid for Gold, Silver and Lead Ores and Sulphurets.

— MANUFACTURERS OF —
BLUESTONE,
LEAD PIPE,
SHEET LEAD,
SHOT, Etc., Etc.
 ALSO MANUFACTURERS OF
Standard Shot-Gun Cartridges.
 Under Chamberlin Patent.

JOHN TAYLOR & CO.,
 IMPORTERS AND DEALERS IN
ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,
 ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
 CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of Assayers, Chemists, Mining Companies, Milling Companies, Prospectors, etc., to our full stock of Balances, Furnaces, Muffles, Crucibles, Scoria, etc., including, also, a full stock of Chemicals.

Having been engaged in furnishing these supplies since the first discovery of mines on the Pacific Coast, we feel confident from our experience we can well suit the demand for these goods, both as to quality and price. Agents of the Denver Fire Clay Co. and for the Morgan Crucible Co., Battersea, England. Also for E. G. Denniston's Silver Plated Amalgam Plates. The plates of this well-known manufacturer are thoroughly reliable, and full weight of Silver guaranteed. Orders taken at his lowest prices. Our Illustrated Catalogue and Assay Tables sent free on application.

JOHN TAYLOR & CO.

NEW DISCOVERY.

Mines Revived and Miners Enriched

By the wonderful **MacArthur-Forrest Process**, Controlled by The Gold and Silver Extraction Mining and Milling Co. H. A. W. Tabor, Pres.; LEONARD GOW, V. Pres.; H. A. Jones, 2d V. Pres.; P. GEO. GOW, Technical Mgr. and Asst. Treas.; T. L. WISWALL, Gen'l Mgr. and Secy.; PETER MCCOY, Treas.; W. L. COOPER, Eng.

TRADE MARK.
 The Cassel Gold Extraction Co., Also in Australia, South Africa, New Zealand, Queensland, Etc.

General Office of Company:
 Rooms 8, 9 & 10, Tabor Grand Opera House Block, DENVER, COLORADO.

Also mills in operation as follows, viz: The Denver Mill, Denver, Colo.; The Livingstone Gold Mining Co., Boulder Co., Colo.; The Puzzler Gold Mining and Milling Co., Boulder Co., Colo.; The Cripple Creek Gold Extraction and Power Co., Colo.; Calumet Gold Mining Co., Middle Creek, Shasta Co., Cal.; The Shasta Gold Ex. Co., Middle Creek, Shasta Co., Cal.; The Mercer Gold Mining Co., Fairfield, Utah; Chample's Mines, Humburg District, Yavapai County, Ariz.; The Crowned Kline and Last Chance Mine, Yavapai Co., Ariz.; The Union Mines, Maricopa Co., Ariz.; The Revenue Con. Gold Mining Co., Revenue via Norris, Mont.; The Creighton Mining & Milling Co., Creighton, Cherokee Co., Georgia; and others in course of erection.

The object of this company is to introduce the Mac Arthur-Forrest process. We have purchased from the Cassel Gold Extraction Co., of Glasgow, Scotland, the exclusive right for the United States to use patents covering this process.

If you desire an experimental test communicate with the secretary. If the results of the tests are favorable, we will then make arrangements to treat a quantity of not less than five tons at Denver.

We are fully prepared to grant royalties to mine and mine owners, or rights covering districts and counties. The process consists of pulverizing the ore to a fineness of about 50 mesh, and then subjecting the same to an action of a very diluted solution of cyanide. A few tubes especially constructed according to our diagrams, for triturating, settling and filtering, is all that is required extra in connection with any kind of pulverizing stamps or rolls.

The total cost, as a rule, does not exceed from \$2.50 to \$5.00 per ton.

The most desirable class of ores for this process is the so-called refractory gold ores, pyrites, hematites, manganese and tellurium. We have also treated successfully dry silver ores.

We will be pleased to answer any inquiries and furnish any desired information. Address,
T. L. WISWALL,
 P. O. Box 926. Gen. Mgr. and Secretary.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist nor the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Silver Ores," "Leaching Gold and Silver Ores") that have been "unusually popular" is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assay; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Lead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Copel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 130 12mo. pages, with illustrations, well bound in cloth; 1889. Price, \$1, postpaid. Sold by DEWEY PUBLISHING CO., Publishers, No. 220 Market Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Etc.

SECOND EDITION—JUST OUT.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is separate from Part I, and treats of Gold and Silver Bullion, Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion; Assaying Bullion; Humid Assay of Silver; Gay Lussac's Method; Volhart's Method; Manipulation; Lead Ores; Copper Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur; Salt; Note.

One of the methods given for the Assay of Copper is new original and exact, as is also one of the processes for Zinc. The book contains 161 pages with illustrations, and is strongly bound in cloth. Much of the original text is reprinted from new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING CO., Publishers No. 220 Market St., San Francisco.

Malthine M'For Co.

FACTORY:

Cor. Jefferson & First Sts., Oakland, Cal.

MANUFACTURERS OF

ACID, ALKALINE AND WATER-PROOF PAINTS,

Superior to anything of the kind in the market for

IRON, WOOD AND TIN.

Unequaled for Submerged Timbers. Red and Brown Paints for Roofs, Warehouses, Stables, Fences, Etc., mixed Ready for Use. Also, Sheathing Paper, Portable California Mastic Roofing, the Best in the Market for

RANCH AND CITY.

AND UNEQUALED FOR

Teredo-Proof Pile Covering.

This Company also Manufactures a Malthine Compound for

RENDERING BOOTS AND SHOES WATERPROOF.

The same is a superior article for Preserving Harness rendering it impervious to Moisture and keeping it always pliable and soft.

Send to Factory, Jefferson and First Streets, Oakland, for Samples and Prices.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, Jr.

This new and important book is on the use and construction of Ditches, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, hurdy-gurdy, rockers, undercurrents, etc. also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, postpaid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

MINING AND SCIENTIFIC PRESS.
 The Leading Mining Journal in America. Established 1860. Latest Discoveries in Science and Improvements in Mining and Mechanic Arts illustrated or described. A Standard Illustrated Weekly published at \$3 a year by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.

Electricity.

An Abused Science.

The public is less credulous and superstitious than it was a thousand years ago, says the *Manufacturers' Gazette*, but the difference is not so great, considering our material and intellectual progress, as to be the source of any especial pride to the present generation. It is true we have to a great extent outgrown a belief in constantly-occurring miracles, the worship of holy or unholy relics, and the fear of human and demoniacal witches; but it is an open question if as much ignorance and blind superstition do not exist, although manifesting themselves in different ways, among us to-day as were in the world during the dark and middle ages. Thousands upon thousands of persons would no more think of being married or set out upon an ocean voyage upon a Friday than they would think of eating a dynamite cartridge for breakfast. A similar inherited dread is shown by the same persons for crossing a funeral procession, for being the thirteenth at a dinner party, or seeing the new moon over the left shoulder. These are the persons and they are legion, who enrich the modern astrologers, the so-called "metaphysicians," the faith cure doctors and the Christian scientists. They make a demand for chicanery of various kinds and there are not wanting those who are capable and eager to supply their wants.

The medical profession has probably suffered more from these miserable and mercenary quacks than has any other. The doctors and the science of medicine, however, have endured hardly greater injury than have the reputable electricians and the science to which they have devoted their lives. The public as a whole knows comparatively nothing about electricity. It sees the wonderful things it has and is doing, and naturally it is easily led to believe that there is nothing beyond its power. The mystery which surrounds the working of the force forms thus a very convenient shield behind which electrical shysters may conceal the worthlessness of their contrivances, and thereby easily persuade their gullible victims that, although the claptrops which they have to sell may give no ocular or tangible proof of possessing any value, they yet come under the same laws which control all electrical mechanism.

What these devices are which have done so much to degrade the name of electricity and magnetism, and which are awakening in the intelligent public such distrust of almost everything that is called electric or magnetic, it is not necessary to name in particular, even had we room in a single number of the *Gazette* to do so. There is the long string of so-called "electric" medical wearing apparel, each of which is claimed to have wonderful curative powers because of the electricity or magnetism which is generated while it is being worn. One need but know only the very first principles of electricity to see in an instant that all such contrivances are absolutely worthless, and that the makers depend for their sale solely upon the magic of the word "electric" or "magnetic" attached to the article.

Many of these deceptions have a row of alternate copper and zinc plates sewed on to a cloth which it is intended the invalid should wear around some part of his body, next to his skin, the claim being that the perspiration of the wearer, acting on the metals, will generate a current of electricity which will cure various kinds of ills when all other means have failed. The first thing that strikes one on examining the contrivance is that the circuit being of the same potential throughout its length it is impossible for any current to be generated. The second is that if any current by any possibility did manifest itself it would be of such slight force that it could be applied to a flea without making it jump. The third is that a current, even though many times more powerful than any that could be manufactured by the article, would not leave the metallic surfaces to enter the body, and if it did it would have not curative power whatever, at most only acting as a stimulus to the muscles.

Thousands of persons are made to believe that they can be cured of some disease, or at least relieved from its pains, by wearing in the soles of their shoes a few metallic plates arranged in a certain way, and hundreds of others buy and wear "magnetic" rings for the same purpose. These persons should not have thrown from their pockets their old horse chestnuts, which were a great deal cheaper, and not one whit less efficacious. The dry-goods merchant who bought a lot of flannel, and finding it going too slowly, marked up its price and sold it as "electric cloth," claiming for it wonderful curative powers, well understood the gullibility

of his customers, and reaped a handsome reward for his vicious shrewdness.

This is not the only way in which reputable electricians and electrical manufacturers are made to suffer, and their science is brought into disrepute and suspicion. The country is flooded, so to speak, with condensed electricity, spurious electric and magnetic machines, "electric" this and "magnetic" that, which are made simply to sell, and which prove, so far as practical work is concerned, absolutely of no value. It is not only the buyers of these frauds who are injured by them, but the manufacturers of genuine electrical goods suffer as well, for the disgust and suspicion which are aroused fall like the rain upon both the just and unjust.

The Phenomena of Resonance.

Nikola Tesla, the famous electrician, in an interview in the *New York World*, says:

"In the experiments of transmitting power by means of wires the phenomena of resonance is to be observed. If one tuning fork, for instance, is set into vibration, another one of the same pitch, anywhere within reasonable distance, will respond. That is a familiar phenomena of sound termed resonance. Now, if I set up these etheric vibrations that I speak of to a certain pitch, and my wire is within reach of these vibrations (not necessarily metallically connected) it will respond, provided its pitch corresponds with that of the etheric vibration."

"In that way I obtain energy in another conductor without any metallic connection whatever. Where a single conductor is connected with the source of vibratory energy these waves surge back and forth in that conductor very much as water would in a tube when you reverse it back and forth."

"One of my most interesting experiments is with the incandescent lamp with a single wire to it. I place in the center of this a piece of very refractory substance of any kind and connect that with the source of vibratory energy, and with this as a center, these etheric waves are sent out in concentric spheres and are reflected back from the inner surface of the glass globe upon this small piece of refractory substance. The impact of the molecules of rarified air in this globe creates such intense heat in this refractory substance (which is the focus) as to bring it to a high state of incandescence. It is difficult to find a substance that will stand that heat, but I have found some substances that will stand it fairly well."

"The transmission through the earth can be effected at any distance; in fact, it matters little whether the distance is small or great."

"Such a result, if achieved, would, of course, be of incalculable value to the world and greatly advance the progress of the human race. In this great country (of which I am proud to be a citizen) we have water powers which, in aggregate amount, are sufficient to supply all the needs—in fact, far more than the needs—of the whole human race. Take, for instance, Niagara. This famous waterfall is estimated variously all the way from five to six millions horse power. Now, four millions horse power, economically directed, would light every lamp, drive every railroad, propel every ship, heat every store and produce every article manufactured by machinery in the United States."

"It will not be long before we can transmit that power under quite practical conditions, by means of wire with the alternating system, over distances as great as a thousand miles. Engineers now object to the use of very high pressures, which would be necessary in such transmissions of power. But I believe the time will come when we shall transmit that energy without any wire."

"Since I have experimentally proved that we can get back electric impulses over one single wire without any return, we may avail ourselves of the earth as a medium of transmission as one difficult obstacle to overcome. In fact, the only serious objection to this scheme is to find a means to concentrate the energy of vibrations spread over a great area on one spot."

"If this power is to be transmitted across the ocean it will, of course, involve the expenditure of an enormous quantity of energy. It has been suggested that I can produce a set of lenses made of asphaltum or gutta percha or any other good so-called non-conductor of electricity, and can concentrate these rays, or waves, to a focus where their effect would be powerful."

"This plan, if at all practicable, could be applied as well across the Atlantic as it could at shorter distances on land."

In view of the fact that England possesses one of the, if not the most effective and cheap telegraph systems in the world, it is not without interest to ascertain exactly at

what cost the nation obtains this service. In 1870 the Government bought up the telegraph companies at a cost of something like seven and one-third millions sterling. Since that date the capital account has been increased to close upon eleven million pounds sterling, involving an annual interest and charge of £300,000. The telegraph service of the United Kingdom has, since its purchase by the Government, resulted in a total loss of four and one-half millions sterling. For the year 1891-92 the total loss was nearly £400,000, though the actual excess of working expenses over income was only £90,000. I venture to think, writes the London correspondent of the *Electrical World*, that if these figures were better known to the public they would acclaim with less enthusiasm the ingenious demands of certain gentlemen to still further lower the telegraph tariffs.

Reliability of Tests.

The aversion shown by many to reports of efficiency and other tests has a true foundation independent of a suspicion that the results have been "cooked" for interested purposes. In a test of even simple character a constant exercise of judgment is necessary, while nothing should be taken for granted in regard to the reliability of the instruments used. These remarks may seem trite, yet they are none the less important and their application is too often lost sight of. The former applies particularly where the conditions of a trial are variable, or where a personal estimation of some point enters into the results. In engine trials it is usual to assume the indicator to be correct, yet recently a large number of indicators of a standard make were rejected because not one fulfilled the requirement of a maximum error of two and one-half per cent; the error of a low-pressure indicator may easily be eight per cent, and in any case the readings of an indicator cannot be true at every part of the scale. An example that recently came under the notice of the writer was in relation to the test of an electric-light engine, which proved so unfavorable that the owner thought of replacing the engine by another. An examination of the data showed that the "expert" had taken the mean of two trials, one of 12 hours and another of only several hours' duration; while the former gave satisfactory results, the latter, through wrong estimation of the condition of the fire (or none at all), gave a result entirely too high. In another instance an "electrical engineer" lost his position because the data from his test of a dynamo gave an efficiency of over 100 per cent, on account, it was subsequently discovered, of the instruments reading incorrectly; had the efficiency come within the limit it would probably have been accepted without reference to the instruments. In a certain manufacturing establishment the weekly report of the engineer regularly shows the consumption of refuse coal per horse-power per hour to be between 1.5 and 1.6 pounds, the engine being of the compound-condensing type. These examples may be extreme, but they belong to an important class whose effect tends to cast suspicion on tests generally; even an extended examination of published reports of tests by professional experts of a given type of engine will be found far from reassuring. In order that errors other than those of observation may be checked, all reports, to have serious consideration, should be accompanied by an exact and certified transcript of the original data sheet, on which there should be no corrections, even of supposed palpable errors, which may, in fact, be the means of a proper interpretation and estimation of the test.—*Electrical World*.

Useful Information.

Household Uses of Electricity.

Science has provided man with many inanimate servants, comparatively few being the inventions of earlier ages, the more numerous and important ones belonging to our own times. Among these, obviously, the servants actuated by electricity stand pre-eminent, not only as the latest development of energy, latent and almost unknown in the ages of the past, but as the most generally applicable and manageable of all agents for doing work; and, while in its present stage, it is not a true prime mover, being dependent upon water power, wind power and steam, it serves as an efficient translator and distributor of other forces, so that it can be made to do not only much of the drudgery of life, but to perform the small tasks of every day.

The dwelling without electric bells, electric gas lighters, burglar alarms, the district telegraph for summoning timely aid in the

person of the district messenger, the police or doctor, or that is still without the telephone, is far behind the age; while the house having all these, in connection with electric lights, motors for driving the sewing machine, water pump, clothes-wringer, the mangle, the dumb waiter or elevator, is only fairly modern; but to be strictly up with the times the house must be provided with electrical cooking, water-heating and house-warming apparatus. It must have synchronous electric clocks in all the rooms, and it must also be provided with electric registers for recording certain operations in the house, such as the opening and closing of doors, safes or cabinets, and similar uses, for indicating the level of water in tanks, driving ventilating apparatus controlling temperature and the flow of air, for locating a fire, should one occur, and turning on water for extinguishing it, at the same time sending the alarm to the Fire Department. The electrical piano may take a place in every house; it will be operated by a first-class performer by means of a master piano at a central station, which will distribute the music throughout a large district; and it is not too much to expect that the more pretentious homes may be provided with a full orchestra operated in a similar manner from a distant station.

The story of the summer outing will not be complete without a full line of lantern transparencies, which necessitates an electric lantern for throwing them upon the screen. Every dining table will be provided with electrical heaters and coolers, by means of which coffee, tea and other liquids may be increased or diminished in temperature to suit. Where smoking is admissible, electric cigar-lighters come in place of the old-time match. The hall and conservatory will be provided with electric fountains illuminated at night by electricity, and, in the conservatory and garden, the shrubs and flowers will be illuminated by small lamps placed within the flowers and among the leaves and branches. Electrical clothes-brushes and carpet sweepers are forthcoming; possibly a toothbrush in which the necessary movements are produced by a suitable electric motor might be a desideratum.

The drawing-room, and in fact the entire interior, will be ornamented by means of electrical devices, some of them depending more or less upon electric illumination, while the others require the current merely for producing certain motions. The illumination of pictures will be effected by small lamps inserted within frames of such construction as to throw the light upon the picture and at the same time screen the lamps from view, so that the pictures may be fully and artistically illuminated, while the light in the gallery is made soft and subdued, thus permitting of concentrating the entire attention upon the pictures which will then be seen to the best advantage.

It is improbable that ere long the lady of the house will be enabled to see from within a visitor at the door, through the medium of electric wires, and that the weight and general dimensions of the person may be appreciated at once, so that the desirability of a personal interview may be determined upon in advance.

By a modification of some of the existing autographic telegraphs, or by a new invention of the same class, a letter written in one home can be instantly transmitted to another at a distant point, thereby outdoing the most efficient mail service. With the current accessible, it is not improbable that every family will have its electrical carriage always ready to roll out on the street and travel a number of miles without fatigue or danger.

Where the house is not fully modernized, and the occupants persist in burning coal locally in the furnace or range, instead of having it burned more economically at a central station, the heat now wasted will be utilized to the last degree in generating currents for lighting purposes and for power. The feasibility of this scheme has already been demonstrated, and improvements are constantly being made which, without doubt, will result in final success.—George N. Hopkins in *The Independent*.

WHILE the Chinese system of smelting (tin) is similar to that of the Malays, it is more elaborate and carried out on a much larger scale. In place of the bamboo bellows, a very ingenious plan is adopted. The trunk of a tree about 18 inches in diameter and 10 feet long is carefully hollowed out and closed at either end. A long pole with a circular piece of wood at one end, fitting exactly into the bore of the tube, acts as a piston. In order to secure the tube being perfectly air-tight, the end of the piston is well padded with feathers. Valves are placed at each end to allow the air to enter, and in the center the nozzle of the bellows

communicates with the furnace by means of a small air passage. On the piston being drawn out, the air in the higher portion of the tube is forced down the nozzle, and, being drawn back, the air in the further part of the tube is similarly drawn into the furnace. The charcoal is soon brought to a white heat and ready for the molds.—Consular Reports.

AMERICAN INVENTORS.—Many great American inventors have earned world-wide fame: Fitch and Fulton for steamboats, Whitney for the cotton-gin, Evans for milling machinery, Whittemore and Jenks for looms, Terry, Ives and Jerome for clocks, Wood for plows, Lorillard for tobacco-making, Edwards for leather-making, Blanchard for lathes for turning irregular forms, Spencer for geometrical lathes, Hoe, Adams and Gordon for printing presses, Collins and Root for ax-making, Ames for shovels, Woodworth for wood machinery, Fairbanks and Howe for scales, Howe and Crosby for pin-making, Knott and Mott for stoves, Stuart for sugar-refining, Baldwin and Winans for locomotives, Pullman for sleeping cars, McCormick and Ketchum for reapers, Colt, Spencer, Sharp, Smith and Wesson for firearms, Phillips for matches, Wells for hats, Goodyear for India rubber, Ericsson for naval construction and hot-air engines, Howe, Wilson, Singer, Gibbs, Grover and Baker for sewing machines, Morse for the telegraph, Taham for lead pipe, Whipple for screws, Chickering and Steinway for pianos, Burden for horseshoes, Yale for locks, Roehling for wire cables, Corliss for steam engines, Disston for saws, Stephenson for horse-cars, and Gatling for quick-firing guns.

SMELTING METALS BY ELECTRICITY.—A new process of smelting and casting metals is described by *Invention*. It is called the Tausig system, after the inventor, a German, whose place is at Bahrenfeld. The method of treatment is claimed to produce, by a single process, in a quarter of an hour, with an expenditure of some 300 cwt. of coal per 1000 cwt. of finished cast metal, bronze, iron, steel, copper, brass, zinc, platinum, gold or silver, free from air flaws, blowholes or babbles. The process is stated to be effected electrically by means of metal electrodes placed in an exhausted furnace, large molds being set up outside the same and exhausted simultaneously by one process. Castings up to 30 pounds of iron have been made, it is reported, within 15 minutes, the air pump in use showing 92 per cent exhaustion of air, amperes 2500 and voltage of 2½. Mr. Pogson, the British Vice-Consul at Hamburg, reports the matter to his government.

A FRENCHMAN states that there are 51,000 breweries in the world. Germany easily leads with 26,240, which produce 4,750,000,000 litres of beer yearly, a litre being equal to about 1¼ pints. England comes next with 12,874 breweries and an output of 2,600,000,000 litres; then the United States with 2300 breweries and 3,500,000,000 litres; Austria, with 1942 breweries and 1,300,000,000 litres; Belgium, with 1270 breweries and 1,000,000,000 litres; and France, with 1044 breweries and 800,000,000 litres. In Bavaria the annual allowance of beer per head of the population is 221 litres; in Berlin, 191; in Belgium, 169; in England, 143; in Switzerland, 31; in Denmark, 33; in the United States, 31; in Sweden, 11, and in Russia, 5.

To the World's Fair!

WEEKLY EXCURSIONS!

Are you going? If so, call on or write to the undersigned before arranging for your trip. The "SANTA FE ROUTE" is the only line under one management from California to Chicago! Palace and Tourist Steepers through to Chicago every day without change! Excursions every Tuesday. W. A. BISSELL, O. P. A., 650 Market Street, Chronicle Bldg., San Francisco, Cal.

Sampling Works for Sale.

The works are situated at Daguerre, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower engine and 45-horsepower boiler with ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. OILSEY, 1914 Stockton St., San Francisco.

Complimentary Samples.

Persons receiving this paper marked, are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. If already a subscriber please show the paper to others.

Voltaic Mineral Rods.

Important to Miners and Treasure-Seekers. Send Stamp for Circular to E. A. COFFIN, No. 47 Bristol Street, Boston, Mass.

Certificate of Copartnership.

WE CERTIFY THAT WE CONSTITUTE A PARTNERSHIP transacting business in this State. Its principal place of business is San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are Samuel B. Connor, residing at San Francisco, California, Andrew S. Grant, residing at San Francisco, California. SAMUEL B. CONNOR [SEAL] ANDREW S. GRANT. [SEAL]

July 12, 1890.

State of California, City and County of San Francisco.—We, On this 12th day of July, in the year one thousand eight hundred and ninety, before me, George T. Knox, a Notary Public in and for said City and County, duly commissioned and sworn, personally appeared Samuel B. Connor and Andrew S. Grant, known to me to be the persons described in, whose names are subscribed to, and who executed the within and annexed instrument, and they acknowledged to me that they executed the same.

In witness whereof, I have hereunto set my hand and affixed my Official Seal, the day and year in this Certificate first above written.

[Notarial Seal]

GEORGE T. KNOX,
Notary Public.

I, M. C. HALEY, County Clerk of the City and County of San Francisco, State of California, and ex-officio Clerk of the Superior Court in and for said City and County, hereby certify the foregoing to be a full, true and correct copy of the original Certificate of Copartnership of Samuel B. Connor and Andrew S. Grant, filed in my office on the 12th day of July, A. D. 1890.

Attest my hand and seal of said Court, this 20th day of April, A. D. 1893.

M. C. HALEY, Clerk.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is specially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference; Fundamental Laws of Hydraulics Demonstrated and Expressed in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities and Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend-Circular and Angular Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

Mining Superintendent

I am desirous of obtaining a position as Mining Superintendent. I am a graduate of the Columbia School of Mines, and have had 15 years practical experience as superintendent of mines and mills. Special experience as expert in concentration and amalgamation.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practices before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S. F.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Calaveras Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (20 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for twelve months. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

MARSHUTZ & CANTRELL.

The Patentee and Manufacturers cordially invite miners to critically examine and pass judgment upon this improved system of milling and amalgamating ores in the following particulars:

1. The cost is less than one-half of stamps of same capacity.
2. The freight to mine is less than one-half of stamps.
3. The cost of erecting is less than one-fourth of stamps.
4. The power to drive it is less than one-half of stamps.
5. The wear is less than one-quarter of stamps.
6. There is no wear except on shoes and dies.
7. In point of amalgamation it is superior to any other machine in use.
8. In its simplicity of construction.

We challenge competition with Stamps, Ball Pulverizers or and other ore crushing machines now before the public.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flange of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphurets and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

VOLCANO.—Amador Record, May 11: We visited the Irma mine at Pioneer and found them taking out some good ore. The quartz is well loaded with sulphurets and sprinkled with visible gold. The ledge is about two feet thick. They have sunk on the ledge incline, which is about 71 degrees, pitching west. They are now running a crosscut and developing good ore. They will soon have backs enough to reap a rich harvest. They own about 1500 feet square of ground. Their facilities for working are good. Plenty of wood and water are at hand. About 23 men are now hired, but when ready to put out rock a larger force will be utilized. The Volcano Hydraulic Company has ground that will give the working of many years. Peck's claim, too, is extensive. He has about 31 acres, 20 of which are available for mining. About 15 acres are covered up with debris from rich hydraulic mines on the hills. The tailings are rich, from the fact that there was so much clay in the original bank which balled and picked up the gold in the flume out at the dump. Those mines were worked from '62 to '77. Much lost quicksilver is to be found. It was in those claims that diamonds were found. These immense beds of tailings have a body of lime which, if conveyed down Sutter creek in a flume, would make an admirable macadam road. Mr. Peck bought this property in '62. He owns an auriferous channel running up through the town, which must eventually be worked. He has two water rights and abundance of free water in the wet season. He needs, however, a monied partner to help him equip the claim with a new flume about 1300 feet long. His claim would then prove a veritable bonanza. The Robinson mine has suspended work.

KENNEDY.—Amador Record, May 11: It is now somewhere near six years since the Kennedy mine fell into the hands of its present owners and under the superintendency of J. F. Parks. The whole property was then in a very much demoralized condition, it having been sunk on to a depth of 850 feet and nothing found to really warrant further development. The present company secured a bond on the property for \$100,000 and immediately proceeded to sink another hundred feet. On the strength of the developments made on the new (950) level they concluded, with some misgivings as to the result, to buy the property. From that day to this the mine has steadily improved in output and appearance until it now ranks as one of the greatest gold mines in California. The latest development is the sinking of the north shaft 200 feet deeper from the 1550 level. On the 1750 level a drift and crosscut were run to tap the ledge. Where the vein is now opened up at that depth the showing is equal and probably better than anything thus far developed in the upper levels. This latest strike gives solid backs of virgin ground from the 1550 to the 1750 levels, which means sufficient ore for two years' run and probably an increased gold output over any like period in the mine's past history. Superintendent Parks was over from the Kennedy on Monday last and made a personal examination of the Wildman mine, in his capacity of resident director. Mr. Parks expressed himself as being greatly pleased with the recent developments made, and at the flattering outlook for the future of the property, and also with the good judgment displayed in its general management. Good reports reach us from Plymouth district. More prospecting and really active work are under headway in that section this spring than for several years previous. Plymouth has experienced some hard times for a few years back, but it looks as though her luck was about to turn into a good streak again. Superintendent Myers has put several men on at the Bunker Hill mine and it is understood that everything is being put in shape preparatory to starting up the mine in earnest. This will be hailed as welcome news by our country readers. A 60-horse-power engine and boilers have been purchased for the Bay State mine at Plymouth.

PROSPECTS.—Amador Ledger, May 12: The matter of finding a mine is, as a general proposition, a speculation which is attended with a degree of uncertainty as to results, and as the coveted gold is so anxiously sought, men and corporations are spending fabulous sums in an endeavor to find mines. In Jackson, within a stone's throw of this office, lies a piece of property of 80 acres which has had three prospect shafts about 50 feet deep, and a tunnel about 40 feet long, upon it for years, each having been made upon the several different ledges upon the property. When these works were constructed the decomposed quartz through which they ran proved to be very rich, while the ledge upon which they went down showed a good prospect. The property referred to is the Meek ranch which joins the Zeile property on the south, commencing about 500 feet from the Zeile shaft. It is bounded on the south by the Moore mine. The eastern side of it is 1500 feet long north and south, while the western side is 2200 feet long. The three ledges on the property extend north and south, just as do all of the "mother-lode" ledges. The tunnel to which we refer is just across the creek from the Zeile mill. This property is owned by Chas. Meek and Ellis Evans, and they ask but \$10,000 for the entire tract of 80 acres. Any one desiring to secure information relating to the purchase of this property, can apply to Ellis Evans at the National hotel, Jackson. The above is not the only property within a short distance of our town which is worthy of investigation by those who want to find a mine.

There are a vast number of similar prospects on the "mother lode," which would pay capitalists to investigate. Dave Fisher and N. Shea are delighted with their recent strike in the Irma. The Griesbach ledge which they have struck is about two feet in width and is very rich, being about the same quality as that found in the Zimmult mine near them. In addition to the Griesbach ledge they have struck another equally as rich. Negotiations are now in progress by the company looking toward the construction of a 10 stamp mill. The lessees of the Bunker Hill mine, near Amador, have begun work on that property, under the superintendency of John Myers. They are now busy at the Mayflower shaft, out of which they are taking the water and putting the hoisting machinery in readiness for steady work. The company expects to visit the property in a few days and make definite arrangements as to its future developments. J. H. Zumalt, who is mining in Pioneer district and hauling his rock to the James mill, had several tons of ore crushed last week which turned out about five ounces of gold to the ton. Mr. Zumalt is getting out the rock, hauling it to the mill and having it crushed at a total expense of \$4.50 per ton. At the Hardenberg, Supt. Fuller is continuing the sinking and is now down about 60 feet below the last level, as it was before Haywards took hold of the property.

Butte.

THE BISHOP MINE.—Oroville Mercury, May 13: By a fire yesterday afternoon at the Bishop mine, on the hline lead, near Bangor, the extensive hoisting works and arrastras on the property were totally destroyed. The fire originated from the smokestack, and when it was discovered it was beyond control. The Bishop was considered one of the best mines in that locality, and is the property of Mrs. Bishop and her sons, the Will brothers. On Sunday the pump broke down and it was repaired so that operations could commence again Thursday. The value of the works, including the machinery, is placed by W. W. Will at \$5000. Twenty men were thrown out of employment by the disaster. We understand that there was a partial insurance on the property. It is more than likely that the works will be immediately reconstructed.

THE ORO MINING COMPANY.—The directors of the Oro Mining Company yesterday let a contract to Wesley & Morgan, of Forestown, for development work on the ledge of the company situated near Enterprise. The contract calls for the running of a new tunnel 100 feet on a new lead and for the extension of the old tunnel 50 feet. The Oro is one of the best ledges in eastern Butte, and if the development work shows up the ledge as expected, a new mill will be erected and extensive operations inaugurated.

Calaveras.

GYPSUM MINE.—Calaveras Chronicle, May 13: E. H. Davidson of this place has located a gypsum deposit on Esperanza creek, about nine miles from this place. The lead is about 16 feet wide and can be readily traced for a distance of 5000 feet. Gypsum is a sulphate of lime and contains about 25 per cent of water, and when burnt to drive off the water and then ground up it forms what is known as plaster of Paris. There are a number of various colors, but that shown us by Mr. Davidson was snow white, fine-grained and translucent, and constitutes alabaster, or the finer grade of gypsum, and is used for making vases, mantel ornaments, etc. Mr. Davidson has a large specimen on exhibition at the postoffice in this place.

THE BEATRICE MINE.—Prospect, May 13: Work on this mine, on the San Domingo, is still continued, though at present the force is reduced and the mill is not running. The upper tunnel is being pushed, and rock is being taken out. Work will soon begin on the big tunnel which will be run on the vein the entire length of the three mines, or 4500 feet. This tunnel will develop not only this mine, but may be the means of opening up several more on the same group. The location is peculiarly favorable for tunnel development, owing to the steep mountain, and the tunnel will be nearly a thousand feet below the croppings. Abundant power is at hand for the power drills which will be used.

RICH QUARTZ.—Angels Echo, May 13: A man brought to our office the other day a piece of quartz, which would perhaps weigh three or four pounds, that was more than rich. It must have contained at least \$400. And the funny part of it is that the lucky finder would not show us the quartz until he had enjoined perfect secrecy upon us in regard to his identity and the location from whence it was taken. We shall, however, take the liberty of informing the public that the quartz was found in the Bear Mountain range.

Del Norte.

CHAOME.—Del Norte Record, May 13: It is rumored that the Altaville chrome mines will be opened this summer; if so, it will be a great help to Del Norte, as this will necessitate the employment of from 100 to 150 men. Seventy-five tons of machinery arrived by last steamer; also machinery for the black sand mines on Crescent City beach.

El Dorado.

PAOMIARO.—Georgetown Gazette, May 11: We are pleased to hear that the old pioneer miner, T. Z. Armstrong, is opening up a ledge southwest of town which shows good promise. It is about time Tom was making another strike, and if he doesn't, it will not be for lack of practical, well-applied energy. A. Baldwin arrived from Calistoga on Monday. Mr. Baldwin is the man who, a few years ago, with Tom Armstrong, took out a \$23,000 pocket below town. Our old friend is looking trim and hale as of yore, and we are inclined to believe he is up with a view to uncover another pocket.

Nevada.

WILL GET A GOOD MINE.—Transcript, May 9: The company that purchased the old Tom

Hughes gravel mine, and bonded the underground of the Morgan ranch, owned by the Nevada County Land and Improvement Association, are progressing finely. Dan Coffin is superintendent of the property and is confident of developing a No. 1 gravel claim. The channel is an extension of the one developed in the old Alta Hill, and extends through to the Town Talk ridge. The company have run their tunnel in about 900 feet from Deer creek on the opposite side and just below the Wyoming mine. They are employing a good force of men.

FINA NDOOTS.—Some very fine nuggets of gold were found in the Utah gravel mine, just above the Central House, a few days ago, and the mine looks better now than at any time since work was commenced upon it. There are four other companies at work in the vicinity of the Utah, and it is confidently believed that before the summer is over there will be a pretty good gravel-mining boom in that part of our county. There is no question about there being as good gravel mines in the Washington district as there are in the county, and time will demonstrate the fact.

WILL RESUME OPERATIONS.—Peter Long, superintendent of the San Jose drift gravel mine, arrived here from San Jose last evening. This morning he went to the mine and intends to begin operations at once. A crew of men will be put to work, and the development of the mine pushed ahead vigorously. Mr. Long informs us that the company is in good condition now and intends to do everything on a cash basis.

LOOKING FINA.—The West Harmony gravel mine continues to look fine. A contract has just been let to add five more stamps to the cement mill, making 15 in all. There is not much being said about this great mine, but the owners are mighty well pleased with their property.

SAVING FINE GOLD.—Grass Valley Telegraph, May 13: There is an apparatus in operation on Deer creek near Newtown that is reported to be most successful in saving fine gold. We do not nor could not learn the names of the inventors, but we are told that the system is a very simple one and consists of a series of sluice boxes peculiarly arranged. It is said that the two gentlemen who are working the arrangement have made \$100 in 11 days by just shoveling the sand, dirt or whatever may be handy into the flume. Where Chinamen, who are about as close workers in river beds, can only make \$1 per day, these parties, with their new process, make \$5 per day. Our informant says that the process is an entire success, and that the finest gold can be saved in any place. The parties operating on the creek are located near the Bagley place.

DEVELOPMENT.—Nevada Herald, May 12: At the Wyoming mine six men are working. They are taking out ore right along, and have quite a large dump of it. J. M. Buffington is superintendent. The Home people are prospecting their claim, just below the Providence. They have started a tunnel at the creek level, and will run into the hill about 150 feet and then crosscut both ways for the ledge. They are now in about 80 feet. There is a great deal of work going on at the Providence at present. The company are working both the front and back of their mine, and have large ore bodies. The mill has been put in shape, and is now running 30 stamps and 12 concentrators night and day. About 75 men are employed. The new chlorination works will soon be ready for business. The building and furnace are finished, and the tanks are now being put in. Superintendent Davis and F. W. Bost superintend the job, and the new furnace is pronounced a model one. The sulphurets-room is full, and Director Wideman thinks they will hardly be able to catch up with the output of the mine when they get to working the sulphurets. The Providence is still a big mine, and the prospects are that it will hold out for years to come. It is rumored that a company will resume work on the Pittsburg mine on the Town Talk ridge. The tributaries there have been doing remarkably well of late, and the owners feel encouraged to run a couple of new drifts in the lower levels. The Champion continues its steady output of bullion, and the surface improvements are nearing completion. The buildings cover lots of ground now. When all complete, work will be commenced on the plant for the old Merfield, it being the company's intention to operate both mines. The Champion will be a big mine then.

THAT OBEY THE LAW.—The few hydraulic mines which were running and impounding their debris, in this section, shut down promptly on May 1st, and are now awaiting, with the patience of Job, the coming of the Debris Commission.

THE MARYLAND.—The annual meeting of the Maryland Mining Company, Grass Valley, was held last evening, and the following officers were elected: Directors, Geo. D. McLean, Chas. H. Mitchell, T. C. Dorsey, L. V. Dorsey and S. P. Dorsey; president, S. P. Dorsey; superintendent, S. P. Dorsey; secretary and treasurer, L. V. Dorsey.

IDAHO-MARYLAND.—Telegraph, May 13: In an interview last week with Mr. Eugene C. Celler, superintendent of the Idaho mine, he informed us that they were now taking out most excellent ore from the lower depths of the mine in the Maryland ground. On Thursday they struck a fine ledge of gold-bearing quartz in the east drift of the 1400 level, and last evening there was a great strike in the 1500 level. The ledge in both places is large and is filled with gold. Many specimens were taken from both levels, and in fact the whole huge boulders of quartz taken from the ledge might be regarded as "specimen ore." The mine is indeed looking exceptionally well.

A DIVIDEND-PAYER.—Grass Valley Union, May 14: The W. Y. O. D., which is a dividend-

payer, is one of our best mines and a great help to the town. Quite a number of men are employed at good wages, and the mine is looking unusually good. A new condensing boiler, a new Corlies hoisting engine and a pumping engine have been purchased and will be put in use at the mine. No dividend was declared this month on account of the expensive improvements now under way, and the company has purchased some expensive property adjoining the mine. Mr. Dan Coffin is superintendent and is running things very satisfactorily.

IDAHO MINE.—This famous property, which has recently changed hands, still continues to bear as rich as ever. On Thursday they struck a fine ledge of quartz, bearing gold in large quantities, in the Maryland ground. Some rich rock was also struck in the 1500 level which is unusually good. The ledge is very large in both levels and a number of fine specimens have been extracted. Mr. Eugene Celler, the superintendent, understands his business and seems to know where the gold lies.

THE SOUTH IDAHO.—Some time ago we gave an extended account of this property, but since that time improvements have been made which are worthy of notice. A new steel whim was put up a short time ago and it works to perfection. The shaft is down to a depth of 55 feet, and they have a ledge which is two feet in width. The ledge shows free gold and is excellent looking rock. Eight men are employed all the time. No rock will be crushed for some time yet, as the company expects to erect a mill in a short time. Drifting will be commenced when they have gone to a depth of 100 feet.

OSEOEN HILL MINE.—Work at this mine is being pushed very actively, and it is destined to become one of the best mines in the district. During the short time in which they have been working the mine some extensive improvements have been made. The shaft is now down to a depth of 170 feet and the caved ground is almost all cleared, there being only two sets more to be taken away. Mr. Goldstone, superintendent of the property, informs us that this section will be the liveliest in the district in a short time. The buildings which have been erected are very heavy and substantial and are put up to stay. Very heavy machinery has been set on the works, and we will hear shortly of some very promising developments.

THE BALTIMORE.—This mine is situated on Squirrel creek, in Rough and Ready township, about 34 miles below town. They are running a tunnel, which is now 700 feet long. The ledge is about ten inches in width at present, but is expected to widen out before very long. A new mill will be erected as soon as the lumber can be brought from the mill, where it is being cut. Mr. Lakeman will have the iron work ready to put up as soon as it is needed. The mine is superintended by Joseph Snyder, and at the present time four men are employed. A raise has been made to tap the ledge, which will go right through to the surface. This shaft will be used as an air shaft. The mine, we are informed, can be run cheaper than most any mine around here, and for that reason an enormous amount of ore will not have to be taken out to pay expenses.

Placer.

THE MAYFLOWER BOSSING MACHINE.—Colfax Sentinel, May 13: A machine that will bring about a great saving in drift mining is at present in use at the Mayflower mine, Forest Hill. It is a boring machine consisting of a portable engine and boiler combined and a portable tower 40 feet high with gearing for the drill, which alone weighs 1100 pounds. The machine when working will bore a hole six inches in diameter and from 15 to 25 feet a day in mountain cement or in rock wet or dry. There is a pump eight feet long and five inches in diameter, the drills and this pump, working like an ordinary pump, fills with the sand and is then emptied. Whenever it is desired rocks the size of a hen's egg may be taken out, which increases its usefulness in prospecting. The machine enables the owners to prospect the pitch of the bedrock or channel, and works as well at 1200 as at 200. It has proved itself a success and will prove a great saver of energy and money in prospecting. It has been on the divide for about two months, and will continue to be used over there as it belongs to the Mayflower Co. It can be put up in two days and taken down in one and requires but two men to run it. At present it is run by a man from Pennsylvania who has had much experience in boring wells. It consumes but little fuel, and no doubt will aid materially in developing the mineral resources of the divide.

CLAIM JUMPED.—Herald, May 11: On Tuesday, May 9th, George J. Morgan relocated the old Floyd mine, known as the New Hope quartz mine. The ledge is situated in Township 12, Section 16, just at the rear of the jewelry shop of E. Lundquist, about a mile below Auburn, on Auburn ravine. Morgan has christened his mine "The Wilson." Early this week he took a couple of tons of ore to the Lavalle quartz mill, which does custom work, had it crushed and amalgamated, and claims to have realized \$32 from the rock. Some time ago Morgan offered the owners of the land \$500 for ten acres on which the ledge is located. His offer was refused. In an interview with W. H. Huchin last Thursday morning Morgan offered to pay \$100 per acre for two acres, but he wanted \$150. The readers of the Herald are familiar with the litigation which followed the location of the mine by E. P. Floyd in April, 1889, and also the recent decision from the Secretary of the Interior declaring the land owned by George Keener to be agricultural land. The case will probably be taken into the courts, but with the recent decision from the Department of the Interior it looks as though Morgan will have

the hard end of the battle. Attorney F. P. Tuttle represents Morgan and J. M. Finweller the Keeshners.

San Diego.

GOLD GALLOA.—Julian *Sentinel*, May 11: A couple of weeks since we made a note of 140 ounces of gold bullion making its way to San Diego. Last week Smith, Plant & Frary made a cleanup of over \$7000 for two months' work in the Ella mine, the property of S. N. Wilcox. The boys were working the mine on a lease. Little has been said of late regarding this property or the boys who were hammering away firm in faith of future reward, we preferring to let the results speak right out in meeting. This they have done in a manner very gratifying to those interested and to the further credit of the camp. We regret that the bullion was not placed on exhibition in San Diego as an evidence of what muscle and pluck will accomplish in the Julian mines. This ore ran \$120 per ton, but the extreme modesty of the boys knocked the camp out of a big advertisement. We again remark that had any other locality in this southern country produced a like amount of gold under similar circumstances, the newspaper columns would have been filled with it for weeks and scores of mining men would have been attracted to the camp thereby. We again remark that the gold is here, in quantities that will pay, and the judicious application of capital and muscle will bring it to the surface. Only to-day one of our leading merchants' borrowed our drug scales to weigh a lot of gold brought in by a chlorider. This is a fact, and proves conclusively that Julian mining interests are not dead but sleep only. There is not a month in the year but what this camp adds to the gold of the nation, and if Mr. Carlisle gets into trouble after he has put into circulation the "gold reserve," of which we hear so much of late, all he has to do is to call upon Julian and she will respond in a manner that will paralyze the Wall-street shysters. If one-half the energy and capital of San Diego county that is being wasted in the vain effort to accomplish the impossible was concentrated in the development of our known resources the result would be surprising, but it is a shameful fact that not one dollar of San Diego capital can be enlisted in her home enterprises. How can her people expect capital to come from other quarters to develop her water enterprises or her mineral resources when home capital is lying idle, too timid to leave the bank vaults?

Shasta.

IRON MOUNTAIN.—Shasta *Courier*, May 13: A report was circulated this week that Iron Mountain was going to start up, but, as we anticipated, the report was too good to be true. We understand, though, that the owners intend to make some improvements up there, among them being a large dust chamber, which will save and retain the rich and valuable dust that used to escape in working the ore. Wm. Chynoweth has secured another lease on the Golden Chariot near Ft. Dingee, and is doing some work on the property. This mine belonged to Wm. T. Coleman, who secured a U. S. patent to the claim and did considerable work on it before he met with financial reverses. We expect to be able to record some lively operations in mining properties in this vicinity within the next few weeks. Mill Davis and George Slocum have been repairing and putting the Spring creek ditch in order. The ditch supplies water for the Calumet, which, according to reports, will resume operations soon. C. G. Farmer sold to A. Lievsay the Rob Roy and Comet claims near Rock creek, about a mile north of town. The claims have not been worked to any great extent, but show flattering prospects, and the ledge, which is from one to two feet wide, promises to develop into a young honauza.

Siskiyou.

GOLD MINING.—Yreka *Journal*, May 10: The gold mining claim at Greenhorn, in which Messrs. Raynes and Austin are interested, is now progressing nicely. They are working a large force of men opening up the claim. It is now paying more than expenses, which speaks well for it. We hope this claim will develop into a good paying property, as it gives employment to a number of men, and those who are risking their money should be amply rewarded. We consider the mining interests of this county of great and lasting interest to the county. Gold taken from beneath the earth and put in circulation is so much permanent wealth added. E. H. Hughes and others are interested in the development of quartz ledges in Greenhorn. They have several ledges that prospect well, and they expect to put a number of men to work soon. San Francisco parties are looking into these claims with a view of purchasing. Siskiyou county has millions of gold buried in her hills and valleys and only awaits development. The American Bar Co. of Portland, Or., which is putting in a wing dam in the Klamath river, a few miles below Henley, will soon be ready for operations. It has put in a 50-foot wheel, and has pumps and everything ready for work. The Hunt mine on Middle Fork, Humboldt district, has a shaft down 150 feet, and is running a crosscut 12 feet from the bottom. It employs 18 men, and is running day and night. It has a ten-inch ledge that prospects exceedingly well. Clark & Co., near the same place, are running a tunnel, and are developing a fine ledge that pays \$18 to \$20. John Boyle of North Fork, Humboldt, has a tunnel in 600 feet, and will run it at least 700 feet farther, and will strike the ledge at a depth of 600 or 700 feet. He is much bothered with snow, which is four or five feet deep yet. He has leased the Spencer mine, and will put on a force of men at once. The shaft is now down 300 feet, and he will continue sinking the shaft, and expects to strike a good-paying ledge. The mine has shown a fine paying section. Messrs. Phillips and Cartwright, of the North Fork, are getting out timber, preparatory to stopping out the

quartz, which shows a splendid prospect. Hegler Bros., of the same district, have opened a fine quartz ledge in their tunnel, and are taking out a large quantity of quartz, preparatory to crushing in their splendid mill. Jessemann & Humphry, of the same district, are working the lower tunnel, stopping out the ore, which will undoubtedly yield well. Mr. Foure, of the Knapp mine, is working on his lower tunnel, and is opening up a well-defined ledge, which will pay \$12 to \$15 per ton.

Trinity.

GRAVEL CLAIMS.—Cor. Trinity *Journal*, May 13: Six miles below R. L. Thomas' place, on lower New River, I reached Steve Noble's home place. Mr. Noble has 66 acres here, 30 of which is good paying gravel. It has never been washed except in a small way. He also owns the water-right of Panther creek, from which, he informs me, a ditch of one and a half miles would bring the water to the claim at 250 feet of pressure for eight months in the year. There is a good dump right into the river. The banks are from 20 to 40 feet high and the gold heavy. He estimates that an expenditure of \$4000 will put the claim in good running order. A little below Noble's house, and on the opposite side of the river, is the Mason Bar claim, owned and worked by W. J. Nichols. This property is located at the mouth of China creek. He estimates that about two or three seasons' run will about work this claim out. Two ditches of three-fourths and one mile in length bring the water of China creek to the claim with a pressure of 120 feet. There are about 1000 feet of 9, 11 and 15-inch pipe. The flume is 80 feet long, with a 12-foot undercurrent. There is a splendid dump into the river. The creek furnishes about 700 inches of water for four months of the year. The banks are from 10 to 60 feet in height, the best pay being of course near the headrock, but the gravel prospects from grass roots down. He estimates that it pays from 12 to 15 cents per cubic yard, the gold bringing \$17.67 per ounce from the mill. The gold is rather coarse, pieces of \$9, \$11 and \$14 having been found in cleaning up. When he has washed this claim out, he proposes to remove to another claim which he owns at China Bar, about half a mile below his present work, which prospects still better than the Mason Bar claim. The same water which he is now using will be taken there. This water covers about 109 acres of good pay gravel. One mile below Noble's place is the Hoboken postoffice at Mosee Patterson's. Mr. Patterson has been here many years. He owns the Granite Slide claim of 20 acres on the west bank of New river, and about six and a half miles above its mouth. There is not more than a quarter of an acre washed. The banks of gravel, so far as they have been washed, are from 15 to 25 feet high, and, I am informed, prospects well. The ditch is 2 1/2 miles long and brings the water from Bell's creek. The water is good for about six months of the year, and can be brought to the claim with as much as a thousand feet of pressure if such a great pressure is necessary. Pieces of gold as high as \$3 in value have been found here. Mr. Patterson also owns the Hoboken Flat mine of 36 acres. This is located about a mile farther down the river, and is said to prospect well. Between Panther creek and Hoboken, a distance of two miles, there are about 300 acres of gold-bearing gravel, which, if a company should purchase the claims and water-rights of Messrs. Noble, Patterson & Nichols, could be covered and controlled by the only water to be obtained. These rights and mining claims should by all means be consolidated and washed by one company. They could be purchased for small sums, and would not require the expenditure of many thousand dollars to place them all in good working order should a company take hold. They could also purchase R. L. Thomas' claims and water-rights at Portuguese Flat, six miles above Noble's (mentioned in my letter last week). They would thus control the water and gravel of New River from its mouth up for a distance of 12 miles. This would be an excellent opportunity for the investment of capital.

IRON QUAATZ.—Trinity *Journal*, May 6: We were shown some very rich quartz this week by Ezra Thomas of Shasta county, who has been in this county for several weeks prospecting. The quartz was from a ledge about 2 1/2 feet wide, which Mr. Thomas discovered recently in the Lower Trinity country. Mr. Thomas is a prospector of 20 years experience, and says that there are lots of good mines in this county which in time will be worked with big profit.

BEAUTIFUL GOLD.—Another cleanup was made at the Hubbard mine the first of this week which was more than satisfactory. From a 20-days run about \$6000 was taken from the flume, giving \$300 per day with a very light expense. This mine is only one of many in this county, as will be thoroughly shown when water in sufficient quantity is brought on to the ground. Lack of water has caused many rich locations to lie idle and undeveloped, but the time will come, and soon, too, when such ground will be worked so as to yield a handsome profit.

Tuolumne.

BONDEN for \$6000.—Tuolumne *Independent*, May 13: The Columbus quartz mine, owned by Smith Bros., at Cherokee, has been bonded to Wm. Johns for \$6000. Mr. Johns represents a wealthy English company, which means active business. They have a bond for one year, and the work of development has already commenced. An engine has been put on the mine this week, and it will be in running order by to-day. The shaft is now down 92 feet, and will be put down 100 feet deeper before drifting. The hanging-wall vein is six feet wide, and the foot-wall vein is ten feet in width. The pitch of both will bring them together at a greater depth. For years this mine has been worked at a profit by arrastre. With a width of vein from which to readily extract large quantities of ore, mill-working will yield a large

revenue over the slow arrastre process. This has always been considered a valuable mine, and we feel satisfied that Mr. Johns (who, by the way, knows much about Tuolumne's old mines, from his long mining experience here) has made a wise selection in developing the Columbus.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—Virginia *Chronicle*, May 13: 1500 level.—Have continued to extract ore and old fillings in working upward in the old south stope, from the 10th to the 16th floors, above the sill floor of this level. 1650 level.—Have continued making necessary repairs to the drifts on the sill floor of this level. We continue to extract some ore from the old stope, eight floors up in the upraise, No. 6 carried up from the main north-west drift; also from the old stope in working north from the crosscut run west from the north-west drift. A south drift started at the end of the crosscut run east from a point 60 feet up in the upraise which was started from the drift from these north workings, 27 feet above the sill floor of this level, has been advanced 50 feet in porphyry and some quartz. Have continued to extract some ore of fair quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main north-west drift. Have extracted during the week from all parts of the mine 511 cars of ore about 500 tons. Shipped to Morgan mill 656 1440-2000 tons of ore. Average assay value, per railroad car samples, \$26.95. The assay value per battery sample of all the ore worked at that mill during the week (655 tons), was \$24.08 per ton. Bullion now on hand in our assay office, value about \$12,000.

OPHIR.—1565 level.—The west crosscut started from the bottom of the winze, sunk 52 feet below the sill floor of this level, has been advanced 28 feet; total length, 68 feet; in a porphyry, clay and quartz formation. The men heretofore employed in repairing the west drift from the Ophir shaft on the 500 level have been engaged during the past week in making necessary repairs in the shaft, it being joint work with the Mexican Company.

MEXICAN.—On the 1565 level.—West crosscut No. 2 from the north drift from the east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 23 feet; total length, 219 feet, continuing in porphyry formation carrying clay separations. The men heretofore employed in repairing the west drift from the Ophir shaft on the 500 level have been engaged during the past week in making necessary repairs in the shaft, it being joint work with the Ophir Company.

UTAH.—340 level.—West crosscut No. 3 from the north drift, from west crosscut No. 2, at a point 195 feet in from its mouth, has been extended 15 feet; total length, 151 feet; in quartzite and clay formation of very low assay value.

SIERRA NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 11 feet, making the total length 337 feet; the face is in hard porphyry. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 17 feet, making the total distance west of the joint shaft 3173 feet; the face is in porphyry and stringers of quartz.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level, has been advanced the past week 17 feet, making the total distance west of the shaft 3173 feet; the face is in porphyry and seams of soft clay.

ANDES.—On 420 level west crosscut from east crosscut No. 1 north, has been advanced 10 feet. Total length, 35 feet; formation in face is hard porphyry with small seams of quartz.

GOULD & CUAAY.—200 level.—During the past week west crosscut No. 5, started in north-west drift, 432 feet from main west drift, has been advanced 11 feet; total length, 471 feet; face in hard porphyry. Suro tunnel level.—Connection has been made between our winze from the 1600 level and the joint north drift from Suro tunnel. We are now getting ready to make some needed repairs to this drift.

BEET & BALCHAA.—200 level.—At a point in north-west drift, 230 feet from our south line, started west crosscut No. 2 and advanced same 20 feet, passing through porphyry and quartz; total length, 80 feet. 900 level.—West crosscut No. 4, started in south-west drift 112 feet from west crosscut No. 3, has been extended 18 feet; total length, 46 feet; face in soft porphyry. Suro tunnel level.—Connection has been made between the joint north drift and the Gould & Curry winze, which was carried down by them from the 1600 level. This gives us a good ventilation for this part of the mine. We are now getting ready to do some necessary repairing to this drift.

HALL & NOACROSE.—1800 level.—Are working in the upraise in west crosscut on our south boundary. This upraise has been carried up 24 feet, the top continuing in quartz. 1300 level.—We have retimbered the shaft and station a distance of 15 feet east of the shaft. We are now retimbering the shaft above the 1300 level. Main incline.—We continue making repairs where necessary.

CHOLLA.—Are repairing north drift, 850 level. The east crosscut near the south line, 930 level, is out 200 feet; face is in soft porphyry and seams of clay.

PORCOT.—The north drift from east crosscut, 850 level, is out 54 feet; face is in porphyry and clay. The south raise 80 feet south of Potosi winze, 930 level, is up 74 feet; formation in the top is porphyry and streaks of low grade quartz. The north and south drifts 200 feet east of Potosi winze, 930 level, have been connected. North raise, 1000 level, is up 75 feet on the stope; formation porphyry and low-grade quartz. South raise, 1000 level, 20 feet south of

top of raise from 1100 level is up 28 feet; top shows six feet of fair-grade ore. The east crosscut 1000 level, 160 feet north of top of raise from 1100 level, is out 21 feet; face is in hard porphyry.

Silver King District.

HIGH GAAR.—Pioche *Record*, May 11: Geo. Jones, of Silver King district, has ready for shipment a considerable quantity of very high-grade silver ore. Is black sulphurets and is exceedingly rich. Silver King produces such ore frequently, a fact which causes its backers to stay with the district, and the result must be that the mother lode of that section must sooner or later be found. William Wheatley was in from Silver King district yesterday and returned this morning. He reports progress on the smelter there as somewhat slow, but that it is equally sure. The smelter stack is up, and several retaining walls and grade are prepared for the engine which, however, is not yet on the ground. It will be two months yet, at least, before a start will be made.

Bristol District.

CORPAA FURNACE.—Pioche *Record*, May 11: Charley Roe started up his copper furnace at Bristol Tuesday evening, and in the first 12 hours' run had 10 fine bars of copper bullion. Everything is going smoothly and the run will be highly profitable. Coal is hauled from the P. C. smelter at Pioche. Some custom ore will be worked also before the run closes. The claims from which this copper ore comes were located originally for silver only, but appear to have changed in character, and what the result of extensive work would be, whether to open up more extensive copper deposits or to revert to thin silver seams, is hard to determine.

Cedar District.

RIOR.—Silver *State*, May 13: Charley Harvey is in from Cedar district, about 20 miles due west from Humboldt house. This is a district of which very little has been said, though it is one of the richest in the county. A silver mine must necessarily be very rich to pay its owners to ship ore from it with the white metal quoted at 33 1/2 cents per ounce, yet that is what Charley Harvey and his partner, Jack Poole, are now doing and have been doing for some time. Their ore nets them from \$125 to \$150 per ton, and carries as high as 60 per cent lead, this latter paying all the expenses of shipping and reduction, amounting to nearly \$50 per ton. They make their shipments to the Selby works at Vallejo Junction. L. A. Blakeslee also owns a mine in the district, from which he has just had 20 tons of ore taken out for shipment.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MAY 9, 1893.

- 497,229.—MORDANT—E. Boursier, Los Angeles, Cal.
- 497,166.—AUTOMATIC GAIP OPANEA—W. P. Courtney, Oakland, Cal.
- 497,234.—TILA CONSTRUCTION FOR WALLS, ETC.—J. A. Flint, S. F.
- 497,124.—CULTIVATOR—C. Hohson, Watsonville, Cal.
- 497,125.—STOVEPIPE SHELF—C. N. Johnsou, Seattle, Wash.
- 497,195.—WATAA MOTOR—J. W. McCoy, Berkeley, Cal.
- 496,888.—SELF-OILING JOBANAL BEARING—A. Morrison, Los Angeles, Cal.
- 497,199.—APPARATUS FOR STEMMING RAISING—E. Niehoff, Tacoma, Wash.
- 497,249.—APPARATUS FOR RAISING SUNKEN SHIPS, ETC.—E. Niehoff, Tacoma, Wash.
- 497,209.—WOOD-SAWING MACHINE—D. M. Prosser, Reno, Nev.
- 497,129.—ELASTOPLATING APPARATUS—A. R. Reams, Elmira, Cal.
- 497,031.—GATE—A. Rickert, Clements, Cal.
- 497,077.—FASTENING FOR JAR COVERS—H. Schammel, S. F.
- 497,064.—SPECULUM—M. E. Van Meter, S. F.
- 496,923.—FRAM ESCAPE—Watgren & Haglund, Seattle, Wash.
- 22,410.—DASIGN FOR BADOA—C. A. Gay, Seattle, Wash.
- 22,408.—DASIGN FOR SPOON—W. S. O'Brien, S. F.

The following brief list by telegraph, for May 16, will appear more complete on receipt of mail advices:

California—George W. Arper, Oakland, fancet for oil cans; Mark S. Brndick, Alameda, feed apparatus; Edward L. Burgers, Los Angeles, trap for basins, baths, etc.; Gustav H. Carlson, San Francisco, spillage basket and basket hamper; William A. Bobbe, Alameda, fruit-plting machine; George H. Johnson, Sisson, railway snow-banger; William P. Miller, Redding, ore separator; James E. Phelps, San Francisco, parlor game; Charles W. Prentiss, San Francisco, shirt; Percy W. Ross, Los Angeles, refrigerator car.

Oregon—Campbell E. Christman, The Dalles, fruit-drier; Charles Harmon and A. McRae, Milton, cultivator; Nathan L. Baber, Corvallis, amalgamator; Tice S. Riddle, Eugene, wagon-roed; Greese Riggs, deceased, Crowley S. Briggs, executor, Bu; Thomas G. Sortor, Baker City, filter.

NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

ANY man fitted to take the general superintendency of a foundry and machine shop will do well to read the advertisements in this week's MINING AND SCIENTIFIC PRESS.

In the age of acorns, before the time of Ceres, a single barleycorn had been of more value to mankind than all the diamonds of the mines of India.—H. Brooke.

The Johnston Concentrator.

This new concentrator is the invention of George Johnston, who, as far back as July 9, 1867, patented a revolving belt concentrator "with raised edges and a shaking or rocking motion from side to side." This new machine, lately patented, is claimed to be the most satisfactory one yet evolved from the many types previously in use. The belt frame is suspended from four non-parallel hangers placed in a frame, and by regulating their angle, the oscillation necessary to keep the sides of the belt from being overloaded with sands is obtained, while the oscillation is not sufficient to overload the belt in the center as is the case with the rocker. The result of this motion is a perfect concentrating surface the entire width of the belt.

Small rollers at an angle of about 45 degrees, stand on a slotted base, screwed to the top of the belt frame, keeping up the sides of the belt to prevent overflow. If the belt shifts to either side it can be followed up by these rollers, and answers all the purposes of moulded edges.

The pulp box discharges the pulp in narrow channels four or five inches apart in the direction of the belt's travel, leaving spaces on the belt where the sulphurets can remain undisturbed by the fall of water or sand and pass up to the clear water at the head of the belt; the sand at the same time passing down unobstructed. This machine requires very little attention, is easily regulated, and will do the work of five stamps. With canvas belt it is sold for \$400, but if rubber belt is required it will be furnished at the increased cost.

Mr. Chas. A. Reed, superintendent of the St. Lawrence mine, Ophir, Placer county, is using one of these concentrators behind a 3½-foot Huntington mill. He says: "The sulphurets are very clean, and the loss in the tailings is insignificant—only a few coarse cubes and flakes, but no fine sulphurets. There has been no trouble in adjusting the belt, which frequently runs for more than a shift without adjustment." Superintendent J. L. Grimes of the Drummond mine, Forest Hill, Placer Co., says that "the rocker motion of the Johnston concentrator immediately settles the sulphurets to the canvas belt, which retains them with any amalgam that may pass the plates; it leaves the sulphurets very clean and retains all the fine ores." Mr. Grimes recommends the machine very highly. This concentrator is manufactured in this city by the Risdon Iron Works.

The Standard Amalgamating Pan.

The Standard amalgamating pan, as illustrated in the accompanying plates, embodies all the latest improvements of value now being used in continuous mills. The

THE JOHNSTON CONCENTRATOR.

THE STANDARD AMALGAMATING PAN.

are provided with a steam chamber in the bottom and cones, which affords an increased heating surface, making it possible to furnish the required heat with exhaust steam, which is always used with economy when available. The admission and discharge steam valves are so connected as to create a current through the steam chamber which can be regulated as desired. These pans, as constructed by the Risdon Iron Works, are built somewhat heavier than the five-foot combination pan, and are provided with a wearing ring of cast iron to protect the inside of the staves at the bottom of the pan, as shown; and also with a cast-

iron sleeve to protect the cone as shown. The pan spindle is supported by a bracket cast on the horizontal driving-shaft box, and permits of the removal of the shaft without disturbing the spindle.

A section of the front of pan shows the quicksilver howl with pan siphon in position for draining the pan of quicksilver and pulp, when requiring repairs. These pans are designed with a view to strength and durability. All parts subjected to special wear are protected as thoroughly as possible. Diameter, inside, 5 feet 2 inches. Weight, approximately, 8500 pounds.

THE SEVEN STARS MINING CO.
When the Seven Stars Mining Co. of Arizona was organized, the stock was "guaranteed" for five years by H. H. Warner of Rochester, N. Y.—that is, he guaranteed dividends and the mine was bought and the mill put up. Now it turns out that Mr. Warner has failed, so the guarantee will amount to nothing. The mine must now depend on its own resources, and the investors depend on the mine rather than the man. The mine has not failed that we have heard of, and may turn out better than the man did. However, the mine has been well equipped with machinery, etc., and ought to be able to stand alone. Mr. Warner doubtless had faith in it or he would not have given any guarantee to stockholders, and it is to be hoped there was good basis for his opinion. The investors were mainly Eastern people, unfamiliar with mines, and we should regret to see them lose anything by their venture even if the "hacker" of the enterprise has failed in his own business.

THE TOWNSITE CO. at Kaslo, B. C., have completed arrangements for the erection of sampling works at that point. The capacity contemplated is 100 tons daily. The idea is to furnish a means whereby the owners of small claims can secure quick returns on their

shipments, as an advance of 75 per cent will be made on all ores consigned as soon as the work of sampling is completed. This will make it possible to keep running on comparatively small capital claims which could not await returns from distant smelters.

THE situation in the Kansas coal fields is unchanged. President Walker is preparing to issue a general order calling every union miner in the State out next Monday, and fixing Monday, a week, as time for the Missouri miners to quit.

Comment.

The cyanide process seems to be doing good work in Nevada. At Tuscarora the cyanide plant is running on tailings from the Union mill. The returns from 368 tons, show conclusively that the MacArthur-Forrest process does extract the gold and a large percentage of the silver; assays from the tailings after passing through the solution showing only a trace of gold. Bullion to the amount of \$5,495 20 was melted from the product, a certain amount remaining in the zinc boxes, which cannot be obtained until an entire cleanup is made. The capacity of the plant is being increased by the addition of two ore tanks, one solution tank and a couple of zinc boxes which will be put in this month, after which the yield will be much greater. Says the *Mason Valley Tidings*: "The cyanide process, which is the method adopted for treating the gold tailings at Silver Peak, in Esmeralda county, is doing excellent work there. From a private letter we learn that 90 per cent of the assay value of the tailings was saved at the last cleanup. This is certainly encouraging." There are certain places where the process has not shown satisfactory results because too much was expected of it, or the men in charge did not understand it. Where intelligently handled with suitable ore, it seems to have given satisfaction. Experiments are being made in Calaveras county, this State, which may result in the adoption of this process. Dr. Schiedel, of New Zealand, who has made a success of the process in working sulphurets, has been up at Angels, in the interest of Alvinza Hayward, to see whether it can be satisfactorily used there.

We recently mentioned the fact that the Anti-Debris Association was enjoining many small hydraulic claims in Nevada, Sierra and Plumas counties, and stated that when the Government Commission is organized a license to mine may be procured readily in most of these cases and then operations may be resumed without reference to the Anti-Debris Association. Manager Phipps, of that Association, replies to that article in the *Marysville Democrat*, and among other things says: "The intimation that the Caminetti Debris Commissioners will grant permission to large mine-owners to operate in a way which will be injurious to us or that will discriminate against the small mine-owner is to attribute to that body a degree of official dishonesty and neglect which is unwarranted by the personnel of that Commission."

If Manager Phipps will pay us the compliment of quoting us correctly we will be obliged. There was no such intimation. We were speaking of small mines only, and only of such mines as can build restraining works. The writer happens to know the gentlemen of the Commission personally, and knows that neither Manager Phipps nor any one else can pull any wool over their eyes.

They will be conservative, fair, honest and just. Therefore we have hope for the miners' cause. But Manager Phipps simply uses this quoted sentence to carry a little favor with the Commission incidentally, and really to ask the valley people to continue to support the Association and keep him in employment. He again reasserts the old foolishness about the property of the valley being worth more than all the hydraulic mines. Yet the Government Commission which reported on the subject says the mining property involved is estimated at over \$100,000,000, while the land injured is less than \$3,000,000 in value. We did not say, either, as he asserts, that the large mines were being overlooked by the Anti-Debris spies, but that they were being put in order for work under the law. We still maintain that when the Debris Commission is organized and ready to issue licenses, Manager Phipps will be without an occupation.

R. T. Devlin, attorney for the Anti-Debris people, is informed by some of the Sacramento merchants that in some sections of the hydraulic mining regions orders have been issued by mine-owners that if the local storekeepers buy goods in Sacramento the mines will withdraw trade from them and force their employees to do the same. This is said to be on account of the recent organized opposition on the part of the valley counties to illegal hydraulic mining. The Sacramento Supervisors say that, in consequence, they have been approached by a few Sacramento merchants with the request that Sacramento take no further active part in protecting the Sacramento from injury, as such action on her part is likely to interfere with the sale of goods by the merchants referred to. It is hardly likely, in the *Bee's* opinion, that the leading spirits in the State Miners' Association would countenance the boycott against any one, and particularly against a community that, while manfully protecting its property and its rights, has shown the fair disposition towards such mining operations as would not injure or destroy it, as has Sacramento.—*Sacramento Bee*.

The *Bee* is right in one thing and wrong in another. The State Miners' Association has nothing whatever to do with this. The matter was brought up by one miner before the Executive Committee of the Miners' Association some time since, but was not even considered, no second being given to the motion. It was thought that endorsement of any such action would be undignified and improper, to say the least. So the *Bee* is right as far as the Association is concerned. But the attempt to withdraw trade from Sacramento to which that paper refers, is not on account of the recent organized opposition on the part of the valley counties to illegal hydraulic mining. If there is any such thing it is on the part of individuals who object to the opposition to legal hydraulic mining. The Sacramento people tried to kill the Ford bill and the Debris Commission bill in the legislature and, when passed, asked the Governor to veto them. Both were in line with the Congressional law recently passed, and in line with recent court decisions. Then, when the delegates to the Trans-Mississippi Congress met in San Francisco, a prominent Sacramento merchant was the only one who opposed the resolution about hydraulic mining and asking Congress to build dams to preserve the streams. These various actions seemed to some miners to indicate that Sacramento men were opposed to their mining even under the Caminetti law. If it had been only opposition to illegal mining the miners objected to, they might have stopped trading at Sacramento years ago if they wished. If there is any boycott now, as the *Bee* says, it is not general, is entirely on the part of individuals, and not with the advice or sanction or approbation of the State Association. We are free to confess, however, that we have heard several gravel miners say they would not trade in Sacramento because the people there evinced no disposition to give them a chance to make a living at their business even when they could do it legally. There is now a way to mine legally by hydraulic method, and only one way, and that is to build restraining works. Just now it cannot be done at all because the Government Commission is not yet organized. But the miners should be given a chance to build the works and obtain the licenses. If they fail to do this when they can, why then punishment will follow. If the Sacramento people take a hand in punishing those who break the law, no one can blame them, but those who are trying to do the decent thing should be given a chance to make a living.

News has reached Ruby, Wash., of a marvelously rich strike in the Grand Summit mine on Palmer mountain, in the Okanogan country. They have out 60 tons of ore, the value of which per ton is stated by the telegraph, but it runs up so high into the hundreds of thousands that we are afraid to mention it in a mining paper. The gold is figured by the pound, and such things usually fizzle so quickly that we prefer to chronicle a strike of \$20 rock. People unused to gold mining are apt to get greatly excited at a few pounds of exceptionally rich rock. In California, which has always led the other States of the Union in gold production, and has more gold mines than all the rest put together, if the specimens are very rich we put the mine down as a "pocket claim," that is, a mine

with occasional bunches of very rich rock, and a good deal that is valueless. Some of these mines, notably those in Tuolumne county, pay well, but none pay like those where they have a good wide ledge which shows no gold at all, but will mill ten or fifteen or twenty dollars a ton. These latter are the kind of mines we want in this State, and the only trouble is that most mines will not make as good a showing as that.

A Federation of Miners.

For five days last week delegates from the miners' unions of Montana, Utah, Idaho, Nevada, South Dakota and Colorado have been in session in Butte City. The purpose of the meeting was to organize a Western Federation of Miners, which was harmoniously accomplished. Nearly 50,000 miners are represented in this federation, and it now takes rank as one of the strongest labor organizations in the country. John W. Gilligan of Butte was elected president; T. Manlin of Butte, secretary, and John McLeod of South Dakota, chairman of the executive board. The federation adopted resolutions urging free silver coinage; opposing imported contract labor; opposing repeal of the Sherman Silver Purchase Act and the importation of armed forces in cases of strikes; appealing to workmen not to join State militia organizations; demanding the restoration of the mineral lands in the mining States to the people; condemning the Russian extradition treaty; approving the Supreme Court ruling in the Geary Exclusion Act and demanding an enforcement of the law; and demanding the election of United States Senators by direct vote of the people.

There is considerable "scatter" in the scope of these resolutions. It might have been better for the miners to stick to a few things directly connected with their line of business, without touching anything else. It is a big contract, for instance, to enforce the demand for the restoration of mineral lands to the people. The railroads have been getting hold of these by wholesale for years. The question is the most important one the miners of the West have to deal with. If the miners of all the mining States will pull together, something may be accomplished, but it will be a big job and take a long time.

The question of freight rates on ores is another important matter for all mining communities, but this does not appear to have been touched upon. Modern methods develop great reduction centers, and to get the ores from the mines to these points is a subject in which every miner is interested. Even large properties, with heavy capital, cannot be successfully operated unless freight rates are reasonable. We have an example of this in the case of the Cœur d'Alene mines, Idaho, where they had to shut down and discharge their miners, because they could not pay the railroad rates demanded. If a big mine cannot be worked under such conditions, how can small ones with no capital? And there are two or three hundred small mines to one big one. The subject was well worthy of consideration by a miners' federation.

It is to be noticed that Oregon, California, Arizona and New Mexico were not represented at this convention. In this State there are no miners' unions, but we have had no labor troubles in the mines for a great many years. The miners average about \$3 per day. In Montana, Nevada and some other places they get \$1 more, but how long this will continue remains to be seen.

In Nevada, during the palmy mining days, there was no objection to a \$4 rate, but many claims cannot pay this under present conditions. This rate, combined with the low price of silver, has closed quite a large number of mines in the sagebrush State. The miners are naturally unwilling to see it reduced and the mine-owners have not cared to make a contest, so they have closed down.

We have had no \$4 a day rate in California for a great many years. However, living is cheap here, and with few exceptions the mines can be worked all the year round, conditions which are different from those in the other States. The probability is that some time in the future the underground work will be graded as to pay in Nevada, Montana and elsewhere, and those who work above will get less than those in the lower levels. The high rate of wages at Cœur d'Alene had something to do with the shut-down there as well as railroad rates, though the companies said little about it, not caring to have a labor contest.

The Western Federation of Miners, now that it is organized, will in the future have more or less to say about wages of miners; in fact, that is doubtless its main feature. But if silver continues depressed and silver camps are to be worked, the Federation will have to consider a reduction within the next few years. We are not advocating this, but stating the probability. Mine-owners will not work their claims unless they can see some profit in the business, and with mines closed there is no work for miners at any price.

The Top-Heavy System of Mining.

The mining company which has salaried presidents, superintendents, secretaries, clerks, etc., in the proportion of about ten to one actual miner employed, may be said to be doing business on the top-heavy system. For stock-jobbing operations the system will answer for a time, but not for legitimate mining. It is the adoption of this system, which has brought the Comstock mines to their present condition, and unless it is changed they will go out of sight altogether. There are mines up there which have not produced a pound of ore for years, but which have continually kept a large corps of salaried officials to run them. Of course, this kind of a mine needs very few practical miners, so very few are employed.

There is one company which is said to be paying \$970 per month for rent, secretary, president, superintendent, office boy and janitor, which has never spent any of its assessment money in exploring the ground owned by it, and employs no miners at all.

Another mine with a president and secretary at \$150 each per month, superintendent, foreman, accountant, timekeeper, watchman and shift boss, pays \$930 a month to them and \$208 to two miners. Another pays \$624 to miners and \$2000 a month to officers who are supposed to keep them at work. One of the big mines pays nine miners \$936 a month, while its other salaries consume \$2581 per month. Still another expends \$52 a month for its miners and \$242 per month to take care of them. One pay-roll shows \$52 a month for a miner and \$942 for the bosses. Then there is another with \$624 worth of miners a month and \$1449 worth of other officials. There is also a company which expends \$52 per month for miners and \$813 to keep them in order. Another with three miners, costing \$208 per month, employs supernumeraries costing \$1297 per month. This last mentioned mine has collected over \$1,000,000 in assessments, but has no mine to speak of, never paid a dividend and never will.

It is no wonder that miners are leaving the Comstock, because there is little work for them. The money derived from assessments seems to go mainly to maintain a horde of useless officials who do nothing particularly toward mining development. For development actual miners are needed, yet comparatively few are employed. Of course there must be some, but they are getting fewer and fewer. But the useless officials do not seem to let go. They still hold their positions and draw their salaries.

Meantime, Comstock mining interests are on the decline. Shares which used to be worth dollars are now worth only cents. The top-heavy system will ruin this or any other business. In fact, no other kind of business would have stood it half as long as this has, for, though it has been going on for years, it is still kept up.

If a sudden and radical change in the whole plan could be made, it would do more good to Comstock interests than the striking of another old-time bonanza. Many of these mines could doubtless be made to pay if conducted on any sort of decent business basis, but never can under existing conditions. Some mines on the great lode have made magnificent records as bullion-producers and dividend-payers, while others have made infamous records as robbers of innocent investors and stockholders. The latter have always been run on the top-heavy system, and this alone should be sufficient to condemn them and those persons who manage them. The system is an imposition on the investors and stockholders and a detriment to the whole mining industry.

Foundry Notes.

THE Vulcan Iron Works are furnishing stamp mills and other machinery for the Jones mine in Shasta county, also considerable machinery for the leaching mill of the Ontario Silver Mining Company of Utah, as per designs of Messrs. Salkeld & Behr, engineers. Although Eastern competition and unfavorable conditions have operated to deprive San Francisco manufacturers of considerable trade in the mining machinery line that formerly came to this city from Colorado, Utah, Idaho and other distant points, the general reputation and excellence of their work in this line has enabled them to hold a portion of this trade.

THE Union Iron Works are building a fine steel yacht for Timothy Hopkins of this city, to be called *El Primero*—the first steel yacht built on this coast. The hull is now ready for the boilers and engines, which will be placed in position next week. It is the intention to have the yacht ready to go to sea when she is launched. The *El Primero* is built for speed and it is expected that 15 miles an hour will be made on the trial trip. The vessel is to be fitted with a Roberts water-tubed boiler and will stand a steam pressure of about 200 pounds to the square inch. The engines are to be high speed, triple expansion, capable of turning the propeller 300 revolutions. The hull is entirely of steel, the plates being five-eighths of an inch. The main deck of Oregon cedar is flush from stem to stern, the pilot-house, captain's room and smoking parlor being the only upper works. Below the main deck, abaft the engine-room, are the cabins and staterooms. There are accommo-

dations for eight persons in berths and several more on the divans in the cabin. The inside finishing of the cabins and staterooms will be in polished hardwoods, handsomely paneled. The stateroom of Mr. Hopkins and the one opposite will be fitted with wide double berths and stationary washstands. Two other staterooms with two berths in each are abaft the main cabin. A bathroom and other conveniences are close at hand. The upholstery will be in velvet. The galley and range are amidships. The accommodations for the crew are forward. The yacht will carry a crew of eight men. Incandescent electric lights will be placed throughout the vessel and a search-light at the bow.

THE Risdon Iron works have recently commenced the construction of the Johnston concentrator, which is illustrated on the first page of the PRESS this week.

Coast Industrial Notes.

THE exports of lumber from San Francisco for the first four months of the year were 4,697,000 feet, against 9,959,000 feet for the same period of 1892.

THE city of Alameda is considering the proposition of putting up a salt-water plant for street-sprinkling purposes, and plans are being prepared. The estimate of cost is \$54,000.

THE San Jose Supervisors have decided to deepen and straighten Guadalupe creek, from the northern city limits to tide water, in order to prevent overflows of adjacent lands.

AT the special city election held at Auburn recently the proposition to bond the city in the sum of \$20,000 for the purpose of providing a system of sewerage was carried almost unanimously.

THERE are now 14 vessels in the harbor under charter for grain, 11 being British and 3 German. The tonnage of the above vessels is 23,098 tons and the carrying capacity about 36,900 tons.

THE Pacific Coast Steamship Company's steamers after June 1st will drop San Pedro from their ports of call under a new arrangement with the Southern Pacific, whereby they are to call at Santa Monica.

THE machinery at the Green creek end of the electric line for the Standard mine at Bodie has been put in, and in a few days the whole power plant will be completed. Meantime they are hard at work retimbering the Standard shaft.

THE imports of sugar at this port by sea during April, 1893, were 52,586,990 pounds, against 39,565,315 for same month in 1892. The total imports from Jan. 1st to April 30th were 164,769,812 pounds, against 114,931,758 in 1892 for same period.

OWING to drafts in the Comstock mines, the miners are leaving for Butte, Mont., Park City, Utah, Vanderbilt, Cal., and Kootenai, B. C., which seem to be the most attractive camps just now. A good many of these men have worked on the Comstock for years.

SURVEYOR McTARNAHAN has been looking over the ground on the Stanislaus river, above the People's Ferry, with a view to the establishment of an electric plant. Angels is not to be behind her sister cities, and it is only a question of time before it will be supplied with electricity.

THE Orange county Chamber of Commerce in a meeting gave its pledge to raise \$1500 to secure a title to land in trust for Hill & Co., of Keokuk, Ia., on which to erect a vinegar and pickle factory, the plant to cost not less than \$5000. The deed to the land is not to be delivered till the factory shall have been in operation 12 months.

THE Register reports that Lukes & Wagner, owners of the flour mill recently consumed by fire at Ball's Ferry, talk of erecting a mill at Cottonwood, Shasta county, running it by electric power from a dynamo which will in turn be run by the Battle creek water power. If they do this, it is stated that they will furnish Cottonwood and Anderson with electric light.

THE contract for the laying of the foundation for the new ferry depot has been signed by the Harbor Commissioners. The San Francisco Bridge Company, which is to perform the work, gave a bond for \$180,000, with Behrend Joost, John F. Kennedy and D. A. Warren as sureties. Although the contract is now complete, it will be at least two months before the contractors can begin operations.

OVER three hundred men are now employed in the railroad yards at West Oakland. The ordinary number had to be reinforced in order to keep up with the great increase of business. The yards are blocked with cars and the "hosing down" process has to be kept up constantly. Four overland trains leave daily—two in the morning and two in the afternoon. The proposition to light through cars with gas—the latest innovation in Eastern Pullmans—will probably be taken up sooner than was expected.

SCARCELY a day passes without the formation of some new enterprise for the irrigation of large bodies of land in this State or Arizona. Not only do these enterprises cover vast areas of land so arid that no valuable product can be obtained without the aid of water, but in many cases it is proposed to irrigate lands whose chief boast in the past has been that they did not require that aid in order to be profitably cultivated. The latest enterprise of this character has its location in Butte county, where it is proposed to divert the water of the Feather river, by way of the Big Bend tunnel, and spread it over a large area of land, which will be made highly productive through its agency.

In its current issue, the *Pacific Wine and Spirit Review* says: "After the largest shipping season in the history of the wine business of California, the dullness of summer has come, and the trade of the next two months will be quiet, as is usual in the early and mid-summer. Nearly all the shippers have finished with their orders, and light exports will be the rule from now on. The exports of wine for April were very heavy, particularly by rail, the

grand total being 7885 cases and 1,223,964 gallons, which makes it, with the exception of March, the largest shipping month for bulk goods in the history of the trade. The rail exports are widely distributed and indicate the advantage of low freight rates."

THE danger of an extensive and protracted snit has been averted by a transaction closed in Boise, Idaho, by which the DeLamar Co. becomes the sole owner of the famous Stoddard mining claim. O. M. Hays received \$35,000 for his three-fifths interest last year, and now Tim Regan gets \$87,500 for his two-fifths.

ANOTHER irrigation and water-storage enterprise is being surveyed on the Gila, 12 miles above Yuma, by George Norton. The proposition is to put a 60-foot dam on the river where it is crossed by a natural bridge. The river has a fall of only three feet a mile, and it will consequently back the water 20 miles. The canal will run east of Yuma and into Mexico.

THE City Trustees of Alameda have adopted a resolution that will call for plans for the construction of a city hall in Alameda in accordance with the proposition already passed upon. It provides for the construction of a public building at a cost of \$50,000. As an incentive to architects it is proposed to give to the author of the best plans the work of supervising the construction at five per cent of the entire amount, the second best plans \$250 and the third \$150. The plans will be considered early in July.

THE plans for the new bath-house of the Olympic Salt Water Company have been accepted. The house will cost between \$70,000 and \$80,000. It will front on Bush street for 220 feet and will be 150 feet deep. The tank, which will be its principal feature, will be 150 feet long and 70 feet wide. Its deepest part will have 12 feet of water, and this will shoal gradually to 2 feet. Around the tank will be 200 dressing-rooms. It was reported at the annual meeting of the company that six miles of pipe were being laid. The foundation for the pumping station at the beach is finished, the pumps are ready to be put in place, and work on the excavation for the reservoir is progressing rapidly. The service from the ocean to the Olympic Club will be in operation within 90 days.

A DISPATCH from Astoria dated May 20th says: "Advices from various places on the Columbia give the general condition of the salmon-packing industry. These and the local reports are unfavorable, and create great fears as to the success of this season's business. The rough weather, the freshets and the immense quantities of drift render fishing almost impossible. The damage to nets and traps continues. The traps are catching nothing. Many up-river canneries are not packing at all. The fish-wheels at The Dalles and elsewhere are taking no fish. The canneries connected therewith, which packed 500 cases a day last year, are idle. All things considered, the outlook is discouraging. Should there be no change for the better soon, the pack for the season up to June 1st may be 40,000 cases short compared with last year's output."

AT Pine Ridge, Fresno county, the snow has not yet all gone, but many men have gone into the timber region. The Bonanza mill will be in operation in about ten days. It is the largest mill on Pine Ridge. Bennett, Sage & Humphreys are putting in a mill with a capacity of 25,000 feet a day. The mill will start in two weeks. Demorris is also pushing to completion his mill on the south side of Pine Ridge. It will be in operation in a short time, and its capacity is rated at 25,000 feet a day. S. Lehman has taken to the mountains two 40-horse power boilers for his mill, which is situated near Markwood Meadows. The principal machinery was made by Bond in Fresno. The mill combines a box factory with its lumber saws. The flume men are at work repairing the broken places in the flume, and work will soon begin on the Stevenson creek dam. Ed Figgins, who has the contract of hauling for the Bonanza mill, has a half mile of his log chute completed. J. E. Bretz is arranging to start his shingle mill at an early day. Musick's and Cumming's mills are preparing to start as usual.

Personal.

THE Governor has appointed W. P. Mathews of Tehama World's Fair Commissioner for California, vice John Daggett, resigned.

W. O. RALSTON, Secretary of the State Miners' Association, and James J. O'Brien, the gravel miner, have been up in Plumas county looking at some properties there.

DR. A. SCHEDEL of Auckland, New Zealand, is stopping in Angels, Calaveras county, inspecting the various methods of working the mines and treating the ores.

GOVERNOR MARKHAM has reappointed the old Board of Trustees of the State Mining Bureau, as follows: J. Z. Davis, W. S. Keyes, J. E. Doolittle, W. S. Lyle and Thomas Bishop.

W. R. ECKART, engineer of the Comstock pumping committee, has been on the Comstock for several days past gathering the last data for his report on the feasibility of draining the lower levels of the great lode.

ERNEST WILITE, mining engineer, formerly of Grass Valley, has accepted an engagement with Barnato Bros. as manager of one of their properties in Johannesburg, South Africa. Mr. Wilite sailed for the Cape on the steamship Spartan, April 29th.

JOHN HAYS HAMMOND, the well-known mining engineer, who has been in London, is on his way home from Chicago. It is said here that Mr. Hammond went to Europe to sell the Harqua Hala mines, Arizona. He will shortly go from here to South Africa on some business connected with the Johannesburg gold mines.

CHARLES A. LILLIE and family took their departure from Angels for Shingle Springs, El Dorado county, last Monday morning, where Mr. Lillie will be employed as foreman of the mine recently purchased by Hayward & Lane. Mr. Lillie was for several years underground boss at the Utica mine.

Tuolumne County Mining Interests.

From Our Regular Correspondent.

TO THE EDITOR:—Tuolumne county's past record is familiar to the readers of the PRESS. In this record she has distinguished herself by producing a great many very large "pockets." In consequence of these frequent strikes by the pocket miners, the county has come to be known as "a pocket county." While Tuolumne is the banner pocket county of the State, having in the well-known Bonanza mine at Sonora a property that has produced over \$3,000,000, one mass realizing over \$125,000, the fact should not be lost sight of that she has also a large number of milling veins. These have been equally profitable with the pocket ledges, and the total output greater; but, owing to the fact that their yield was regular and well-known, no mention has been made of their product. To-day, as in the past, the miners delve and hope in the well-known pocket sections, and every month records the strike of the more fortunate pocket miners. While the county is benefited by every miner so employed, it is the present activity along the milling ledges that causes every one to feel that a new era is about to dawn, and Tuolumne's mineral wealth to receive the development required to show her real wealth of gold. In the past, short shafts were sunk on the various ledges, and sums ranging from \$500 to \$100,000 extracted, and the work stopped. At present a class of men have taken hold of these old veins who believe that where so much rich rock was found good milling rock exists, and they have no intention of running away from a good, healthy, old-time pocket. So far their work has proven their surmises correct, and one success has led to the trial of another practically abandoned ledge, until the quartz-mining interests of the county look more promising than at any time in the county's history. Quartz, however, does not hold a monopoly, as the extensive marble quarries near Columbia are now in the hands of a company that is securing the recognition for this unexcelled marble that it should have received long ago. It is well known that Tuolumne has been rich in placer mines, but it is not so generally known that she holds within her borders to-day continuous, unbroken river channels capped with basaltic lava that has scarcely been prospected. On the main channel a large corporation has begun operations on an extensive scale, which must in time attract capital to this vast field of profitable mining investment, and once Tuolumne's quartz ledges, ancient gold-bearing river channels and marble quarries are fully developed and in operation, old Tuolumne will surprise the skeptics who cry, "Pocket county."

COLUMBIA MARBLE WORKS.—Bannister & Fearfield are proprietors of these quarries, which are situated about three miles north of Columbia, on the eastern slope of the Stanislaus river, and about 1000 feet above the same. The supply extends throughout and beyond the 140 acres of the property, and is inexhaustible. At this time three quarries are open on the property. The south quarry is of a very fine-grained black marble; the center of a grained marble; while the north is snow-white Carrara marble.

In consequence of the three varieties and the excellence of the marble, the quarries can fill an order for any variety and in any quantity desired. The quarry is equipped with complete works, which at this time is filling an order for 6000 12x24 inch tiles for the City Hall of San Francisco. These tiles come from the "veined marble quarry." It is to be regretted that the tiles are not from all three quarries, thus showing the variety and fine quality of the marbles. This marble belt is very extensive, extending not alone through Tuolumne, but across the river and almost across Calaveras county. So common and so plentiful is the stone that in this section the rancher and the miner's porkers "point with pride" to the fact that they and their ancestors "dwell in marble halls."

HAM & BIRNEY.—This property, just up the river from Columbia, is fast being developed by that energetic rustler, Mr. W. Sharwood, for Mr. Leachman. At present a Huntington mill is in operation and a full gang of miners employed in the development of the mine.

THE NOONDAY is being pumped out and will be developed by parties who have secured a bond on the mine. The mine is about 11 miles north of Columbia, between the middle and north forks of the Stanislaus river. The old 175 foot shaft showed an 18-inch vein of very rich dark-blue ribbon quartz, and is on the same belt as the Sheep Ranch mine of Calaveras Co. Crossing from Calaveras is an old lava-ash capped river channel that broke away at Columbia and made that camp rich in placer gold and then extended on, unbroken, to Soulsbyville and beyond. Some day this old channel will have its bedrock opened and will well repay the fortunate owners.

SONORA.—Owing to litigation over the principal mines of the town, business has been exceedingly dull for months past, but at present the mines are resuming, and it is earnestly hoped that there may be no further shut-downs.

THE GOLDEN GATE. E. C. Loftus, superintendent, has held the belt and banner as the mine of the county. Just now, Capt. Nevills looks wise, says nothing, but seems to say, "Just wait till the Rawhide gets her stamps to dropping." It won't hurt the Golden Gate to have a successful rival, as the recent litigation has brought out the fact that the Golden Gate, with her 10-stamp mill, chlorinating works and water-power system, has a shaft down 460 feet, with a level run 700 feet on a continuous shoot with an average vein of eight feet of \$16 a ton quartz. Naturally, there has been some contention over so choice a plum and the end is not yet. The mine was shut down (enjoined) from September 22nd to April 15th, but is now dropping its stamps with old-time regularity under a receiver. The question in dispute, "Can a corporation be a co-partnership?" will soon be decided by the Supreme Court, and all Sonora trusts that in the future the mill may run steadily, be it co-partner or corporation.

THE SAN GISEPPA, too, has had to "bide a wee" while the claimants fought it out in court, but at present it looks as though the differences would be reconciled.

THE BONANZA, D. R. Oliver, superintendent, is out of

bonanza at this time. Mr. Oliver is retimbering the old workings and prospecting the grounds to the west, and incidentally taking out gold from the old stopes.

SOULSBYVILLE.—The old Soulsby awaits the coming of some one that will reopen the mine and prospect the 2200 feet of undeveloped ground contained in the property. The past history of the mine is such that there can be little doubt of the success of the work, while the results, if at all equal to the Soulsby's past record, would be most gratifying. Mr. W. Sharwood is the owner. The Blatt & Gilson mill is being removed to the Keltz mine "over on the river," of which Mr. Sharwood is superintendent. The Keltz is well known, and with the Blatt & Gilson mill added to its equipment, will rank as one of the leading mines of the county.

THE BLACK OAK, W. P. Scott, superintendent, is now down about 560 feet, with a strong ledge heavily mineralized. The 10-stamp mill is dropping steadily, with most flattering prospects in store for the owners.

CHEROKEE DISTRICT is midway between Soulsbyville and Summerville. Capital is being attracted to this section with its high-grade propositions, and the region will now be given a waking up.

Wm. Johns, the well-known expert of Plumas-Eureka fame, has bought for himself the Mastodon mine and is erecting a hoist. When men like Mr. Johns select Cherokee as a field for the investment of their individual funds, it is the best possible recommendation the section could have, especially when the investor is as conservative as Mr. Johns is known to be.

THE CARLOTTA, Sutton & Symons, owners, is in litigation, with a decision in sight. The vein is not large, but its contents more than offset that, and once litigation is out of the way and the mine equipped the Carlotta will be heard from.

THE PORTO FINO, W. Sharwood, owner, is one of those "nice little mines" that we would all like to own. The shaft is down 100 feet, with a level run 92 feet, all in one, that averages \$35 per ton. Mr. Sharwood expects to get water for power onto the mine soon, when he will proceed to make a record.

NORTH STAR AND LAURA.—D. R. Oliver is owner of these mines, which are north of and on the same vein as the Dead Horse. Mr. Oliver expects to give these mines a thorough development this season, and as they have the Dead Horse vein running north and south through the entire length of the property, with the Carlotta, Pennsylvania and Porto Fino crossing at almost a right angle, he feels very confident of showing up a very fine property.

THE DEAD HORSE, W. Thomas superintendent, keeps up a very lively kicking, and while all about it are "mum as an oyster," it is generally known that the mine has been and is to-day one of the oldest and best mines in the county. A number of mines in this neighborhood have recently been bonded, and this season will see them developed. Just above Summerville Capt. Nevills has bought the New Albany and is now having the water system put in shape for active work on the mine.

SUTTERTOWN.—Jackass Hill is being given the usual attention by the pocket hunters. At present several companies of Soora capitalists and mine operators are trying their luck at pocket mining on the hill with the usual luck. The pocket miners may not always strike it at Tuttletown, but the traveling man always does, for at this place a sacrifice is offered up morning, noon and night of deliciously-fried chickens with all the trimmings, differing from other hostilities in this: that here they try to see how much they can get in instead of out of you. The natural result is the present increase in the dimensions of the restaurant, while the traveler cries, "Long live Tuttletown."

JAMESTOWN.—There is very little doing in this vicinity. The Columbia Gold Mining Co. and a San Jose company are drifting under Table Mountain and are said to be doing very well. There is a long stretch on the mother lode in this section that will some day come to the front.

QUARTZ MOUNTAIN.—The App, C. A. Nevills manager, was down 750 feet when she hung up her stamps. Capt. Nevills is now down 350 feet in the old shaft and is fast crowding to the bottom. The work so far shows a 16-foot vein of \$10 quartz. If anybody can tell why they hung up their stamps with that to draw on the Captain would like to know it. The mine has fallen into good hands and will soon be showing that all Quartz Mountain mines have needed was capital, grit and brains. The App parallels the old Heslep, which no doubt could be again worked to a profit with present improvements.

THE DUTCH.—The Heslep and App both join the Dutch on the south, so that it contains both veins, which evidently join near the center of the property. The mine has a 200-foot shaft and hoist on a 16-foot vein that mills \$8 per ton. There are numerous readers running to the main vein which are very rich and keep the Owens (Fitzgerald Bros.) busy mortaring rock.

THE HOLMES & MILLER, E. A. Stent, Supt., is south of the App, and, like all Quartz Mountain ledges, is on the mother lode. Mr. Stent is cleaning out the old shafts to see what frightened the former owners away. The north shaft yielded ore that averaged \$126 a ton, the center 30-foot shaft produced \$30,000, while the south shaft returned \$100,000 from but 90 feet in depth. It seems almost incredible that no more work was done, but such was the fact until Mr. Stent took hold. That he will get a mine is a foregone conclusion. A few years ago Angels, of Calaveras county, was like Quartz Mountain—called "only a pocket camp," but a shaft or two has proven it one of the best camps in the State, and it is but a question of very short time until these mother-lode mines of Tuolumne will show that good pockets don't hurt good mines.

RAWHIDE MINE, Capt. C. A. Nevills, manager, has now two shafts, each down 300 feet, with a fine 40-stamp mill ready to operate this month. Just as I came to the shaft the miners came up for dinner, and each brought up a piece of quartz showing gold very freely set in the solid white quartz. In the past the Rawhide was noted for her very rich ore; in the future it is Capt. Nevills' intention evidently to give her a reputation for a large bullion output. The

hoist and mill came on to the mine at the same time, and the captain showed his caliber by taking his time to the mill and crowding the mine. This has not pleased everybody, but the result shows sufficient ore in sight to keep the stamps dropping steadily once they are let go. The plant on the Rawhide is one of the best in the State, and I doubt if the mill can be excelled anywhere.

MARTHA WASHINGTON PLACER MINING CO.—The mines of this company are located on Peoria Flat, about five miles northwest of Chinese Camp. The company is composed entirely of Oakland ladies, who have here secured 700 acres of ariferous gravel ground, 520 acres of which is pay. At this time they are operating by hydraulic process, and have a 75-foot bank of gravel panning gold from the grass roots to bedrock. The gold is bright, amalgamates very freely, and that on the bedrock is coarse. The company has secured a Bennett placer-mining amalgamator, which they will operate in addition. The ground being free of all cement, clay or heavy boulders makes it especially adapted to this or any other process. In addition to this large area of free-wash gravel, a tunnel 1100 feet long has been driven to tap the old Table Mountain channel, where it crosses this property, and bedrock struck showing gravel that goes \$19.50 an ounce. The situation of the mine is complete. Water has been secured for the entire year at very reasonable rates. The pressure is over 280 feet; natural restraining dams are in place and the climate admits of working every day in the year. It is one of those favored mines where "Every prospect pleases and only man is vile," and as the property is managed entirely by the lady owners, every prospect should please in the Lady Washington. It is not possible to do justice to this promising enterprise in this necessarily limited notice and the writer will endeavor to give a more detailed and satisfactory description in the near future. E. H. SCHAEFLE.

Copper River Placers, Alaska.

There is likely to be a big rush of miners to Alaska this season, and if reports are true the Copper River country is about to blossom out as the richest and most prominent gold district in the entire Northwest.

Private advices are to the effect that last fall a party of prospectors, who had been exploring on Copper river all the season with no very great success, had at last struck rich placer diggings about 200 miles up the river and had camped at the spot for the winter.

Before they were forced to quit work, however, they discovered that the entire section of country about them was very rich in gold-bearing quartz and managed to locate several fine ledges. The placer diggings, however, are, so the advices state, the biggest thing of the kind on record.

The entire district seems to be composed of rotten quartz and from \$1 to \$5 a pan can be obtained anywhere. It was late in the season when the diggings were discovered and the party had less than a month to work in, but during that time over \$20,000 was washed out by seven men.

Fraok Wilson, the leader of the party, will come down to Vancouver as soon as possible, and will charter a schooner and send her up with machinery and supplies, while the rest of the party will do the best they can with the means at hand until he returns.

Mr. Wilson will also take up enough lumber to build comfortable quarters for the men, and expects to have a small mill in position and running before the season is over. There is plenty of timber and lots of game, so that there is no danger of starvation, and the river is expected to furnish power to not only run the mills, but also to operate the sluices.

Copper river is not nearly so far north or so difficult to reach as the Yukon, and freight can be carried to the new gold fields for less than half what it costs to the gold camps on the Yukon. Besides this, the season is much longer and the terrible cold and heavy snows that the miners on the Yukon have to contend with are unknown in the Copper River country.

So far no news has been received from the camps along the Yukon this season, but as there were many men there who had very little in the way of food and other supplies to carry them through the winter those who have friends there are anxiously awaiting to hear from them, as it is feared that some will have a hard time to hold out until the season opens up.—Examiner.

MINERAL IS REAL ESTATE.—In a trial before Chief Justice Gooding of Arizona, at Yuma, a jury acquitted two men who had been indicted for stealing ore recently from the Bonanza mine. The defendants had been caught on the premises with the ore in their dinner pails. Lawyer Pierce Evans maintained that no crime had been committed. In the first place, he said real estate cannot be stolen. Gold ore is real estate until broken with the ledge in which it is found. His clients, he insisted, didn't carry the gold away, as it was seized in the Bonanza shaft house. Bonanza miners had been in the habit of taking away ore in their buckets as specimens. For all that appeared to the contrary, the defendants in the present cases might be lugging off gold ore worth \$5 per pound simply as "specimens."

A. MALTMAN will shortly erect below Watt Park, Grass Valley township, one of the most complete reduction works ever put up in Nevada county. The new works will have a capacity of eight tons of sulphurets in 24 hours, and will be equipped with the best and most improved apparatus and machinery, including an improved sampler. Contracts have been made with most of the mines around Grass Valley to work their sulphurets as soon as the new works are ready.

The survey for the San Diego and Phoenix road has now reached into the Otay country. A letter from a Los Angeles contractor contains an offer to grade, bridge and lay the track from San Diego to Yuma under contract, and take one-fifth of his pay in bonds of the company.

The So-called "Sap" of Trees and Its Movements.

An address by CHARLES E. BARNES, Professor of Botany, University of Wisconsin, delivered before the State Horticultural Society of Wisconsin.

The subject which I have chosen to present to you this evening is not chosen so much on account of the information which I am able to impart as for the purpose of correcting a great deal of misinformation which is widely prevalent. Many false ideas as to the nature and movements of what is popularly known as the sap of trees are extant, and in a large number of cases these ideas are founded upon mistaken notions of the physiology of plants. Our own knowledge about many of these matters is yet exceedingly imperfect, and it is for that reason that many of my statements will of necessity be negative. The subject also is one which must have considerable interest for those who are so intimately engaged in cultivating fruit and shade trees as are the members of this society; and I take it that no fact in regard to the life and mode of working of the plants with which we are so constantly dealing will be entirely without interest.

WHAT IS MEANT BY "SAP?"

It will be necessary for us at the outset to gain some accurate idea, if possible, of what is meant by the word "sap." If we think for a moment of its various uses, we shall see that it is a word which designates not a fluid of definite composition, but one under which is included a great variety of watery solutions. The sugar-maker begins even before the snows have left the ground to collect from wounds in the trunk of the maple trees a sweetish liquid which he calls "sap." After a considerable time the proportion of sugar which this liquid contains diminishes very greatly, and he then abandons his work because, as he says, the "sap" has become too poor. The man who has postponed pruning his grape-vines or trees too late in the season finds that from the cut surfaces a watery substance is trickling which he calls "sap." But the sugar-maker will be unable to obtain either sugar or syrup from this fluid, which is, however, called by the same name as that from which he manufactures his sweets. When a boy who is making a whistle hammers the bark of the twig in the spring, he finds it easy to separate the bark, because, as he says, the surface of the wood is then slippery with "sap." The sap of the hoy is widely different from the sap of the pruner and the sap of the sugar-maker.

Again, what we do not call sap may furnish us with some illustrations of the diversity of meanings of this term. We do not ordinarily speak of the "sap" of the apple, or of the "sap" of the grape, or of the "sap" of the orange, but call the fluids which these fruits contain "juice." And yet they are not more different to their composition from those fluids which we do call sap than the three examples already mentioned are different from each other. We might, therefore, in all reason, apply this word sap to the juices of fruits.

We popularly distinguish the older hard internal wood of the tree under the name of "heart wood" from the younger, softer and lighter-colored external wood, which we call the "sap wood." To the fluids which saturate the sap wood we are constantly in the habit of applying the word "sap," but I have never heard it applied to the exactly similar fluids which saturate the heart wood. As far as the composition of these fluids is concerned, there is no reason why that in the heart wood should not equally well be designated as sap.

What then are we to understand by the word "sap?" Evidently not a substance of any definite composition; but the word signifies only in the most general way the various watery fluids which are found in the plant. There is no reason indeed why these solutions should not be called *water*, for in many cases they are almost as pure as the water which we drink. In the chemist's sense, the water which we draw from our wells is a watery solution of various substances, and yet we do not designate it commonly by any other term than simply "water." In a similar manner, it is quite proper for us, and perhaps it would conduce to clearness of ideas, to designate the watery solutions in plants simply by the term "water," understanding it in its popular and not in its strictly chemical sense.

MOVEMENTS OF WATER IN TREES.

Let us turn now to the consideration of the movements which the water in trees exhibits. I shall confine my remarks to trees simply for the reason that they present the greatest variety of water movement and at the same time furnish the greatest difficulties in the explanation of these movements. If, therefore, we understand the movement of water in trees, we shall be able readily to transfer these ideas to the movement of water in the smaller plants, although the statements applicable to the trees are not always applicable to the smaller plants, because of their greater simplicity; however, the greater includes the less.

THE EVAPORATION STREAM.

In the first place, there is need of a very considerable amount of water to supply the constant evaporation which is going on from the leaves of trees. Immense areas of delicate tissue are exposed to the dry air, and oftentimes to the hot sun, in the form of foliage, and from this foliage there is going off at such times large quantities of water in the form of vapor. The water needed to supply this evaporation must come from the soil, because it is not possible for the leaves to take in any water, not even when they are wet by the rains or by the dews. The water enters, not at the base of the trunk where the large roots are found, but only at the extremities of the finest rootlets. At these points the rootlets are clothed with a "nap" or "pile" of fine hairs. These root-hairs must not be confounded with the fine branches of the root, for it is only the finest branches which are covered with the close-set hairs. Consequently, it is only the youngest and most delicate parts

of the root which allow the entrance of the water. But the water escapes from the leaves, and from the point of entrance to the point of exit is a far cry for the coursing droplets. How does it pass through this long space?

It is just here that our knowledge is most defective. We know a number of things that are true in regard to it, and we know a number of things which are not true in regard to it.

We know that it moves in the sap wood of the tree, and neither in the bark nor in the heart wood. Many of you must have made observations which are sufficient to establish this point. You have, for instance, observed that the bark of trees might be peeled off for a considerable distance, and that the leaves would still retain their green color and their freshness. In many cases, indeed, the mere removal of the bark from the tree is not sufficient to bring about its death until several months, and in some trees not until several years after the injury. Death, however, is inevitable sooner or later; but the fact that the leaves remain fresh for so long a time is evidence that the supply of water is not interfered with. Death ensues from a totally different cause, namely, from the starvation of the roots in a way which will be explained later.

Again, you must have observed that it is quite possible to have the entire heart wood of the tree removed, as is often done by decay, and yet to have the leaves remain fresh and green for an indefinite time. In fact, the rotting-out of the heart wood scarcely interferes with the vitality of the tree, except as it renders it mechanically weaker, and consequently more liable to be overthrown by storms. If any further proof were needed, it is perfectly possible to show experimentally that the sap wood alone is engaged in the transfer of the water required for evaporation by cutting into it. A saw-cut which passes through the sap wood, but leaves the heart wood intact, brings about within a very short time the withering of the leaves. In some trees, indeed, a cut which severs only the outer youngest layers of the sap wood will produce the same effect, since in such trees only the youngest layers of the wood carry the water. By experiments on twigs it can be demonstrated that withering will occur even if the bark is almost completely uninjured.

We know the water to supply evaporation moves chiefly in the cavities of the elements of the wood. The wood of the tree is composed of a large number of *fibers*—that is, elongated cells pointed at both ends, and of *ducts*—that is, tubes of great length formed by the breaking together of rows of cells placed end to end. You can get an idea of the manner in which these ducts are formed by imagining a series of round pasteboard boxes piled one on top of another, after which the top and bottom of each is removed, so that, instead of a series of separate chambers, we have now a long tube. The fibers may be likened to a series of lead pencils, sharpened at each end, and placed in contact with each other, the points of the lower ones overlapping the next ones above and fitting in between them. In my illustration the cavity of the fiber would be represented by the lead, and it would be more accurate if we could conceive of the cavity as not extending entirely through the pencil, but stopping short of the point. Minute pits extend from the cavity of one of these fibers to the other, and the walls also of the long ducts are also marked by larger thin spots. It is in the cavities of these ducts and fibers that the water chiefly travels.

We do not know what part is taken in this ascent of the water by those peculiar elements of the wood which you know by the name of silver grain or the pith rays. You will remember these as the shining plates of tissue which extend from the center of the wood toward the circumference. They are particularly prominent in the oak and show most when it is split "with the grain." It is probable that these cells have a great deal to do with the movement of water, but their exact *role* is not fully agreed upon.

We are in almost total ignorance at the present time as to the force by which the water is elevated through so many feet. There are trees in the gullies of Victoria, Australia, whose height exceeds 470 feet, and we must invoke some force which is able to raise water from the level of the soil to the level of the highest leaf. A year ago we thought we had a hypothesis which would account for this movement, but later researches have brought to light some facts which are at present totally irreconcilable with what was a most charming and, at that time, a most satisfactory explanation, and we shall be obliged to abandon it unless the wine of the new knowledge can be held by the old bottles of theory.

At the time when our knowledge of capillarity was greatly extended by the celebrated researches of Jamin, it was thought that we had knowledge of a force adequate to account for the raising of water to these great heights. The fibers and ducts which I have described to you seemed to answer very perfectly the requirements of capillary attraction, and it was thought that this force, by reason of which water rises through narrow spaces, was the one sought. But the rise of water in capillary spaces is proportioned to the size of the opening—the smaller the opening, the higher will it rise. With the decrease of the caliber of the tubes, however, the friction increases enormously, and only small quantities will be able to be moved on account of the diminished size of the tubes. It was quickly seen that, in order to account for a rise of even a hundred feet, the tubes of the wood must be vastly smaller than they really are.

When it was found that the air in a plant is under a less pressure than that outside the plant, it was thought that the force had been discovered, and that atmospheric pressure furnished the explanation. Negative pressure, however, on the interior never reaches zero, and consequently cannot account for a rise of more than 33 feet.

Again, what was called root pressure was invoked to explain the phenomena. It is found that water is absorbed at certain times so rapidly by the roots that it exists in the plant under considerable pressure, and it has been claimed that root pressure, combined with the other forces already known, was adequate to account for the rise of water; but this, too, has failed us.

It is perhaps the greatest weakness of the last theory (that of Godlewski), which we have just had to abandon

temporarily at least, that it depended for its explanation upon the indefinite and illusive "vitality" of certain portions of the plant. Godlewski's brilliant hypothesis, which ascribes to the activity of the living cells of the medullary rays the function of receiving from lower levels the water and passing it on to higher tissues through rhythmic variations in their osmotic power, due possibly to respiratory changes, may yet hold the clue which we are seeking. But when Strasburger jacketed a young tree for a distance of 35 feet, and kept it surrounded by hot water until all of the living cells in the tree trunk were unquestionably killed, and when under these circumstances the water supply to the leaves was not interfered with, so that they remained green and fresh, we were obliged to conclude that the lifting of the water is not dependent upon the life of the tissues directly, but that it is evidently carried on by a physical process yet to be explained.

Before passing from this topic of the movement of water which supplies evaporation, I must allude to a very common and widespread idea—at least I judge it to be widespread, because it is so frequently propounded by my students—that "the sap goes down in winter and up in the spring." Just where the sap is supposed to go in winter is not exactly clear, since, if the roots are absorbing water in the fall when the evaporation is diminished, they are likely to have quite as much water as they can hold already. The conception, apparently, is that all of the water lodged in the trunk and spreading branches goes downward into these roots. It needs, however, only the most casual examination of trees in winter to discover that at this time they are almost saturated with water. The twigs of the hickory tree, for example, will be frozen on a cold day in winter, so that they are as brittle almost as glass, and one can snap off a twig half an inch in diameter as though it were an icicle. The same twig, when not frozen, on a mild day will be so tough that there will be no possibility of breaking it.

Again, if one cuts off a branch from a tree in winter and brings it into a warm room, he will quickly discover that water is oozing from the cut end, showing that the twigs are almost saturated with it. As a matter of fact, the water in trees increases from midsummer or early fall to the beginning of growth in early spring. There is thus no necessity for any "going up" of the sap in spring until the leaves are expanded and the water with which the tree is already saturated begins to be evaporated from the foliage.

BLEEDING.

A second movement of water in trees is that which occurs in the so-called "bleeding." The bleeding of trees occurs at different times of the year, either before growth has begun at all or just as it is beginning. In the two cases the cause is quite different. We find a good example of both sorts of bleeding in the gathering of the sap by the sugar-maker. This gathering begins at the time when the ground is still frozen and the roots are almost or quite unable to absorb any water, but at a time when the air is warmed through the middle of the day by the increased heat of the sun. At first the expulsion of water from wounds made in the trunk is due to the expansion by heat of the air inside the smaller branches and twigs of the tree. This sets up at once a pressure upon the water, and this pressure is transmitted to all parts of the tree. The water with which the tree is filled is thereby forced out as soon as an opening is made for its escape. Later in the season, however, the roots begin their work of absorption, and there is then set up the so-called *root pressure*, by reason of which the water is forced out at the same openings. The latter sort of bleeding is necessarily delayed until growth is about to begin, and is checked as soon as the foliage is sufficiently expanded to begin evaporation.

A bleeding similar to the last takes place at the hood-like tips of grass leaves, where the skin is nearly always ruptured. The little drops of water which accumulate here are commonly mistaken for dew, but are merely droplets exuded from the interior of the leaf, because the falling temperature of the air toward evening has diminished the evaporation from the leaves, while the roots in the warm soil are still absorbing water, and consequently producing an internal pressure. The movement of water in these cases of bleeding, it will be seen, is necessarily toward the point of exit, which may be above or below the point at which the pressure arises.

SECRETION OF NECTAR.

A third sort of movement of water is that which takes place in the nectaries of flowers and leaves. The flowers of our common linden, for example, secrete a considerable quantity of sweet fluid, which is sometimes misnamed "honey," but is properly known as nectar. Honey, by the way, is nectar after it has been digested by the bees. At certain points in the flower there are groups of cells whose special business it is to withdraw water from the parts below, and filter it through their outer walls, after having added to it the materials which make it sweet. The movement of water in this case is extremely limited.

THE TRANSFER OF FOOD.

The last movement of water of which I shall speak is of those solutions which contain the food of the plant. These materials are not those absorbed from the soil, or gathered directly from the air, but they are the substances which have been manufactured by the leaves out of the materials obtained from the soil and from the air. Since these foods are put together in the leaves, necessarily the movement of water containing them in solution must be in a different direction from that which supplies the evaporation. The materials thus manufactured in the leaves must be carried either to those parts which are growing or to those places in which they are to be stored for future use. It is manifest at the first glance, therefore, that the direction of the movement must be in general *inwards* from the leaves, and, since the roots require for their nutrition a considerable amount of these substances, there must be a very decided *downward* movement to supply them.

Now it is plain that these solutions of food must keep out of the way of those portions of the water which are chiefly to supply the evaporation from the leaves. We have seen

that the latter travel in the sap wood. The food currents, however, travel almost exclusively in the inner parts of the bark. You will therefore understand why stripping off the bark, or even cutting it, ensures the death of the tree eventually, even though the leaves remain long unwithered, since the roots depend upon the food formed by the leaves, they perish when severed from their base of supplies.

The movement of the evaporation stream is relatively rapid. The movement of this food current is relatively slow. We do know something of the mode of movement of these food currents. They are apparently brought about through the process known as diffusion, or osmosis, and are therefore necessarily slow. The cause of the movement is practically the same as that for the movement of oil in the lamp-wick, although it is by no means by the same method. The oil in the lamp-wick travels upward because at the top it is being destroyed as oil by reason of the heat of the flame. So the direction and existence of the current of water carrying food is because the various substances dissolved in the water are being altered at the place of growth or storage into new materials. The commonest of these food substances is sugar, and at the growing point of the stem, for example, the sugar is being constantly destroyed as sugar and is being converted into cellulose or protoplasm or some other material. So long as that alteration is going on, just so long will the sugar particles move toward that point.

But I must not impose further upon your patience. I have tried to sketch very briefly, and only in outline, the different movements which the water in the plant is undergoing. I have said nothing of the extreme variety of materials which may be found in this water in different plants, or even the variety found in the same plant at different times, but have endeavored merely to show you that there is going on constantly in the living tree a series of molecular and mass movements, of which too few people have any conception. To our imperfect knowledge let me hope that some of you may contribute facts which shall enable us some day to explain the many things which are now obscure.

The Value of Irrigation.

Maj. J. W. Powell, Director of the United States Geological Survey, contributes to the *New York Independent* of May 7th, an article on irrigation, which is destined to attract wide attention. There may be little in the historical part of the discussion which is new to those who have read standard works on the subject, and little of a practical nature which will be new to the irrigator, but the publication of such an article by such an authority still has a great educational value. Maj. Powell says:

"The earliest agriculture of Europe, Asia and Africa began in arid lands. Turning to America it is discovered that this fundamental art began everywhere under like conditions of great aridity, on sandy plains and hot deserts. In the southwestern portion of the United States, the very last district of the country to be settled by white men, in some portions of Utah, Colorado, Arizona, New Mexico, Nevada and California, where natural vegetation is so rare that it scarcely gives character to the landscape, where sandstorms drive over the country, where naked plains spread under a lurid sky, and where the landscape is often one of naked rock, and where adamantine forms stand in groves and the trees are fossils buried in the rocks, the most ancient agriculture is found. For in the country thus described, the Indian tribes in centuries lost to history, cultivated the soil by artificial irrigation, and developed corn, cotton, potatoes, and other vegetables useful to man, while the rich valleys to the north and east were yet untouched by agricultural labor. Later, and before the discovery of Columbus, open glades here and there were cultivated, but such little patches were far apart, scores or hundreds of miles, and the art was borrowed from the arid lands of the pueblo region. In like manner the desert regions of Mexico and of Peru developed an ancient agriculture; so that everywhere throughout the habitable globe the first agriculture began in arid lands, and the first comparatively dense population was found everywhere in regions where the heavens refused sufficient moisture for crops to grow. This is the greatest paradox of history.

"Civilization sprang from agriculture. Two arts transformed early savage society: Agriculture and the domestication of animals, and the latter grew out of the former. The first fields were cultivated in arid lands, the first flocks were distributed on arid lands, the first cities were built in arid lands and the first civilized governments were organized in arid lands. Under torrid skies, on rainless, treeless plains, agriculture, the domestication of animals, art in metals, temple-building, cities and civilization had their beginning."

After reviewing the ancient record of irrigation and its effects on civilization in the old world, Major Powell approaches the subject of irrigation in the new world as follows:

"On the discovery of this continent the Latin invaders first found arid lands in Mexico, Peru and the southwestern portion of the United States; on a larger scale Germanic peoples found humid lands farther to the north. The Latin peoples from arid lands settled again on arid lands and discovered native people engaged in irrigation, as they themselves had done in the countries from which they came. The Germanic peoples found much less agriculture, only a few petty patches here and there, the art itself borrowed from the arid lands; but they found vast stretches of forest and prairie that could be cultivated without artificial irrigation, and they brought with them the industries of the humid lands from which they came. In the United States no arid lands and no irrigation were known to our people by practical observation until we acquired the deserts of the Southwest from Mexico, where we found the Indian engaged in tilling the soil by irrigation."

He traces the development of irrigation in the United States as a sort of second thought after the tide of settle-

ment had pushed beyond the limits of possible dependence on rainfall. He traces the introduction of the system into the various western States and Territories, and its stage of development in each. This part of the review he concludes as follows:

"The mention of California has been left till the last. When the great valleys, mountains and plains of California were brought under the dominion of the United States by Fremont and his coadjutors, they found a few Indians, a few Mexicans and a few Spanish grandees cultivating the soil by irrigation. Then gold was discovered, and an unparalleled exodus from the East poured an army of gold-hunters into the beautiful land. Towns and cities came into existence like magic. Mining was conducted on an extensive scale, and manufactories sprang up here and there. Gradually the newcomers engaged in the cultivation of the soil, often by artificial irrigation, and the art has made marvelous progress. Extensive and superior hydraulic works are now constructed, and many new devices have been developed by which to distribute water to the growing plants with the greatest economy and to secure the largest amount of agricultural development. Often the waters are carried over the lands in iron pipes, ramifying to the roofs of the trees and the shrubs, and the people of California have fields, vineyards, orchards, gardens and lawns fructified from the springs, brooks, creeks and rivers that are born in the cloud-capped mountains. *The most highly-developed agriculture of the world is now found in some portions of California.*"

Maj. Powell's admonitions to the people of the country, in commending this subject to their more careful consideration, are worthy of reproduction for the large and comprehensive views taken and the fundamental principles outlined. He says:

"This industry is new to our people, and they have yet to learn important lessons which the inhabitants of oriental lands have learned by centuries of experience. Some of these lessons are as follows:

"First—The waters of perennial streams that are gathered thereby, have to be divided among the irrigators. While the waters are abundant and the lands redeemed are but small areas, the distribution of water rights to farmers is apt to be neglected; but the time is at hand when, in many regions of the United States, water rights must be relegated to irrigators by some just method to secure equity and prevent litigation, and even to prevent social convulsions, which are already breaking out here and there.

"Second—The people must learn that the supply of water is insufficient to irrigate all land, and that only a small per cent of the total area of arable land can be converted into irrigable land.

"Third—The people must learn that the seasons of drought fix the limit of agricultural development; that seasons of great rainfall and plenty of water lead to excessive development of irrigation, so that when seasons of drought come, disaster and great suffering result.

"Fourth—The people must learn to construct irrigating works in such a manner that they will resist the forces of extraordinary seasons of flood. In every region a great flood comes sometimes; the maximum supply of water may be reached one year in a decade; when it comes, if the hydraulic works are destroyed, prosperity is transmuted into adversity.

"Fifth—The people must learn the importance of gauging the streams from day to day and year to year for a series of years sufficient to discover the maximum and minimum flow, in order that they may construct their works intelligently, and have definite knowledge of the amount of land that can be irrigated. The maximum must control the strength of the works, the minimum must control the area which can be permanently redeemed by irrigation, and the average flow will give the amount of land which can be cultivated from time to time in excess of the area of permanent cultivation."

California Walnut.

Col. Hatch is making progress with the California exhibit in the Forestry Building at the World's Fair. He has the outside of the structure nearly complete, and, with a couple of days' more work, will have put the finishing touches on the interior. As the California exhibit nears completion, the interest in it to outside visitors increases. It was at first thought that the New South Wales exhibit would prove a formidable rival, but since the California exhibit has taken shape, there is no doubt that it will, when finished, outclass any other exhibit in the building. California fortunately has one of the best locations in the Forestry Building for its exhibit. It occupies a space 52 feet in length by 19½ in width. It fronts on four aisles and is in such a position as to immediately attract the eye of the visitor upon entering the building.

A majority of the exhibits made by other States and countries have but one side of their display prepared for the eyes of the public. With the California exhibit it is different. In it there is just as much to see from the interior as from the exterior. Mr. Hatch has made this a feature of the exhibit. In its general outlines the California exhibit resembles an old-fashioned house. Each of the boards used in the siding is nine feet in height, with ornate molding trimming at the top. The structure has no roof, as that would shut out the light. Mr. Hatch has brought into play a rather peculiar system of dove-tailing in the construction of his house. The woods are all laid together so carefully that they appear as if they had grown together. Not a sign of nail or screw can be seen either from the exterior or interior. The woods, however, are all screwed together.

The wood used in the California exhibit attracting the most attention is the California walnut. Every expert who has visited the building has closely inspected it and pronounced it the finest specimen he has ever seen. Through repeated favorable comments made by visitors about the

walnut, Mr. Hatch has grown very enthusiastic over its future development. French walnut, which has heretofore been considered the finest and most costly of walnuts, does not begin to compare with the California wood, and, since it is known that the French walnut sliced down to the thickness of a thirtieth of an inch sells for 29 cents a foot, Mr. Hatch is of the opinion that there is a fortune for Californians who promote the industry. Mr. Hatch is strengthened in this opinion by an offer made to him by a wealthy veneer house of Cincinnati, which has sought to engage him to go to California immediately and buy up a huge stock of wood while its true value is yet unknown. While Mr. Hatch is not anxious to desert his post at Jackson Park, he will, however, return to California as soon as his work is completed to boom the wood and bring it before the attention of big veneer concerns all over the country.

The Town of Angels, Calaveras County.

Angels has a great name everywhere but at home, says the *Mountain Echo*. We, who have been here these many years, have watched its rise and fall in its primitive days, as well as its rise within the past few years. It has risen, it is true, but far from that station of activity with which it is credited on the outside. We believe in giving our own town a good name, and we desire it to have a good name abroad, but we disapprove of false rumors and unreasonable exaggerations concerning the place as one of great activity, a field that offers employment for countless hundreds of laboring men, farmers, miners, artisans and mechanics. It is true that the mines now in operation in Angels are all paying well, are extensive, and likely to continue in operation for many years, but for the employment offered in these mines there are ample men, and in a business point of view there are already enough business houses, trades and professions to accommodate the amount of business done here; and of competition in the various branches of business really more than there ought to be. There are many mines in this locality, which, if they were all in operation and as well developed as the Utica, Stickle, Matson and Gold Cliff mines, then there would be a good field for more people, more business houses, trades and professions, but such not being the case, these mines lying idle for the want of capital to develop them, we consider that there are establishments enough here at present to fill every requirement, and more, two laboring men to every one job of work.

What class of people do these false rumors that have gone abroad bring to our town? Has it been men of means who are ready and willing to invest in our mining properties, or has it been the class whose only capital is their labor? True, it is the latter; and also a class that care not to work, who are penniless upon entering the town, coming here to better their condition, and at the expense of the honest laboring men they flourish in idleness. There are now of the respectable class of laboring men and mechanics more than can find steady employment; yet the influx continues to pour into Angels without abatement, only to be apprised of the fact upon arrival that jobs are scarce and men to fill all vacancies as readily as they occur. This is the situation here at present, all the flowery rumors throughout the State concerning Angels to the contrary, notwithstanding. These rumors proceed in most instances from parties who know scarcely anything about the place or what is really being done here.

If you have means, want to invest in mining property, or engage in the development of other resources here, then, say we, you can find no better field than Angels; and if you have money and do not care to engage in any pursuit, looking for health and good climate, come to Angels; but if your labor is your own capital, don't come to Angels at present with the expectation that jobs are yawning for men. By the publication of this article, we desire to correct the exaggerated reports that have gone abroad, and give the public an idea of what Angels really is.

The Reno Reduction Works.

The Reno Reduction Works are prepared to reduce ores and will pay the highest price for gold and silver ores consigned to them at Reno. H. H. Beck, superintendent of the works, has succeeded in getting a rate of one cent per ton per mile from the Southern Pacific Company for all ores shipped to the works from points along the railroad. This is as cheap transportation as can be expected, and were it not for the low price of silver bullion the works would doubtless be supplied to their full capacity with ores from mines along the Central Pacific railroad in this State. The percentage deducted from the value of ores for reducing them is low and miners are paid in coin the moment the ores are sampled and their value ascertained.

It is the intention of the proprietors of the works to build smelters for reducing copper, galena and other base ores containing silver as soon as they are assured that ores will be furnished them in quantity sufficient to supply the smelter. They do not, however, propose purchasing undeveloped mines.

There is an extensive copper mine a few miles from Golconda, on the Central Pacific, which is developed to a considerable extent and which would supply several smelters steadily. There are also copper mines within a few miles of Winnemucca, which would doubtless furnish considerable ore—in fact there are a number of copper mines in Nevada which might be made to pay more or less profit if worked systematically and economically, and with the cheap rates for transportation for ores on the railroad employment might be furnished a large number of persons mining and smelting the ores from these mines if furnaces were erected.

The Reno Reduction Works are situated on the Truckee river and are run by water power, which is the cheapest yet discovered. The works are conducted by a practical metallurgist, R. D. Clark, and ores are treated by the most approved modern processes.—Nevada State Journal.

BUILDERS OF

"Sensible" Horse-Power Hoisting Whims.

(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.

The bevel gear on the drum shaft is loose, and, on hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake woods at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horse in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to places for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.

Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and beams, 1400 lbs.

Circulars giving Capacities and Prices furnished on application.

Mechanical Progress.

The United States the Greatest Manufacturing Country.

R. H. Edmonds, a journalist of Baltimore, one of the most eminent authorities on the conditions of recent progress in the United States, contributes to *Engineering Magazine* an interesting and valuable paper, entitled "A Decade of Marvelous Progress," from which a few conclusions are extracted:

The United States is now the leading manufacturing country in the world. We have far outstripped all other nations in the magnitude of our industrial operations. It is almost incomprehensible that in ten years the increase in capital invested in manufactures would exceed the total invested only 20 years ago. The value of our manufactured products increased about 60 per cent; add 60 per cent to the output of 1890 and we would have \$13,700,000,000 in 1900—but that is too much to expect. The rate of growth in mining interests in this decade as in the last would make our mineral output in 1900 nearly \$1,200,000,000, while a smaller percentage of gain, only equaling in volume the total increase in 1890 over 1880, would bring the figures to over \$950,000,000. If our coal-miners add to the output of 1890 as many tons as they added to that of 1880, ignoring in this the percentage of growth, 217,000,000 tons will be produced in 1900. No other country in the world ever advanced in population and wealth as the United States is doing. The progress of the past shows no signs of halting. In fact, the development of our foreign and domestic trade and commerce and of our industrial interests is steadily broadening out.

Contrast our position and condition with Europe, with resources surpassing those of all Europe, with wealth-creating possibilities in soil, minerals, timber, and climate unequalled by Europe, and practically without limit to their profitable utilization, with a homogeneous population of 65,000,000 people unvexed by the arbitrary regulations of half a dozen different governments and free from the drain of standing armies, the United States justly commands the wonder and admiration of the world.

Great Britain is no longer the manufacturing center of the world, for we have taken the foremost position in that line. Its vast iron and steel business is yearly increasing in cost of production, while ours is decreasing. It cannot meet the world's growing demand for iron and steel because it cannot increase its production to any great extent. It produces less pig iron now than it did ten years ago. Much of its ore it imports from distant countries. Its cotton is all imported. It spends about \$750,000,000 a year for foreign foodstuffs. On the continent, every nation is burdened with debt and none of them can ever hope to pay off its obligations. Measured by their natural resources and advantages for continued growth against their debts and the many disadvantages under which labor, they are practically bankrupt. In all of them the cost of production and living must steadily increase. In the United States we have scarcely laid the foundation for our future greatness. In natural resources we are richer than all of Europe; we are paying off our debts faster than they are due; we have barely scratched the ground in the development of our mineral wealth and our agricultural growth can scarcely be limited.

A BIG PASSENGER LOCOMOTIVE.—Engine 999, of the New York Central, is an eight-wheel passenger locomotive. The drivers are four in number, 7 feet 2 inches diameter, tire $3\frac{1}{2}$ inches thick by $5\frac{1}{2}$ wide, secured to cast-iron wheel-centers by Mansell retaining rings; rigid wheel base 8 feet 6 inches; total wheel base 23 feet 11 inches. The engine truck wheels are 40 inches diameter, cast-iron spoke centers, tires fastened by Mansell retaining rings; wheel base 6 feet 8 inches. The weight on the four driving wheels loaded is 84,000 pounds, and on the engine truck 40,000 pounds. The boiler is of the wagon-top type, 58 inches diameter at the smallest ring and has 268 flues 2 inches outside diameter, 12 feet long. The fire box is of the Buchanan type, with water arch; and is set on top of the frame, 108 inches long by 40 inches wide. The total heating surface is 1930 square feet, with a grate surface of 307-10 square feet. The smoke box is extended and is fitted with a deflector and a perforated steel-plate spark-arrester. The stack is straight, 15 inches diameter inside. The exhaust nozzles are double, $3\frac{1}{2}$ inches diameter. The boiler is designed to carry 190 pounds pressure per square inch. The tender has a coal capacity of 6½ tons and carries 3587 gallons of water. It is fitted with a water scoop and is carried

on two four-wheel trucks, each 4 feet 5 inches wheel base, with 40-inch cast-iron spoke wheels and steel tires, the tires secured by Mansell retaining rings. The weight, loaded, is 80,000 pounds, making the total weight of engine and tender 204,000 pounds. The engine, engine truck, and tender are fitted with the Westinghouse air brake, and the engine is equipped with the air signal whistle.—*Railway World*.

Steel Making in the South.

A committee of the Tennessee Coal, Iron and Railroad Company have been making experiments with the Talbot open hearth basic steel process, at the works of the Jefferson Steel Company, North Birmingham, Ala. They report favorably on the process, both in the matter of adaptability to their requirements and in the value of the product. They recommend the erection of a steel plant and suggest that it should have a minimum capacity of 500 tons daily. This can be done at an outlay of about \$1,000,000. The mass of the ores in the South contain too much phosphorus for use by the acid process of steel making, whether pneumatic or open hearth; and while the brown ores are suited to the Bessemer basic process, they are not available to the Tennessee Company, which produces its iron from the much larger deposits of red ores. These do not contain phosphorus enough to keep up the heat in the after blow of the basic Bessemer process, and also have too high a percentage of silicon to permit conversion in the open hearth. It has been proposed to first burn out the silicon in the Bessemer converter, and then finish in the basic open hearth. The Talbot process eliminates most of the silicon by pouring the melted iron through basic slag, which is low in silicon and high in lime and oxide of iron. The silicon which has been reduced in the smelting furnace along with the iron, apparently takes up oxygen from the oxide of iron in the slag, staying in the slag, and the slag also takes up some of the phosphorus and a little of the sulphur, while at the same time the deoxidized iron of the slag is added to the charge, so that there is a gain of iron instead of a loss as by first blowing the charge in the Bessemer converter. This desiliconized metal is then ready for treatment in an ordinary basic open hearth furnace in the ordinary manner. The savings effected by this process over the old basic open hearth process are fourfold. The molten metal can be taken direct from the blast furnace to be treated by this process, thus saving the expense of remelting. With this process the cheapest iron made about Birmingham can be used, that is, gray forge. There is no necessity for the use of scrap when desiliconized metal is used, and the desiliconized metal can be put into the open hearth furnace hot, thus saving a large percentage of the time required to melt a cold charge. Gray forge pig iron, which for some time has been quoted a Birmingham at \$8 per ton, usually contains by analysis about 0.75 per cent of phosphorus, from 1.50 to 2.25 of silicon, and from 0.01 to 0.04 of sulphur. When the basic slag does not contain enough iron it is enriched by adding the necessary amount of brown hematite ore. The resulting steel is reported as of an excellent quality, low in phosphorus and sulphur, with from 0.02 to a trace of silicon.

This process, if it proves as successful in practice as in experiment, will be of great value, to the South in particular, by increasing the demand for its lowest priced iron product, and to the whole country, by increasing its supply of soft steel.—*The South*.

A BIG LOG CHUTE.—The log chute on Klamath river is near Shovel creek and Klamath Hot Springs, in Siskiyou county, California. This chute has an elevation of 850 feet and is 2650 feet long. The logs traverse this distance in about 32 seconds, and as a log chute it is a perfect success. The chute is built of round logs, 30 to 50 feet long and 20 inches in diameter at the small end and squared and hoxed into the butt of the preceding log, which makes a continuous log or stringer. Two of these stringers are placed side by side, securely fastened to the ground timbers, hewed on the inside to permit any-sized log to be shot down into the river. At this time 60,000 feet are run down daily, but it is proposed to double this amount as soon as an engine can be put on the logging railroad now built four miles into the timber. The Klamath River Lumber Company, located at Pokemona, Cal., where the Southern Pacific railroad crosses the Klamath river, is now driving logs from this chute to its boom and mills, 22 miles below.—*N. W. Lumberman*.

METHOD OF SOLDERING ALUMINIUM. Mr. L. Oliven, of 39 Wilhelmstrasse, Berlin, who uses tin, or ordinary tin solder, or an

alloy of tin with zinc for soldering aluminium, dips the article to be soldered under the surface of the melted alloy, and then proceeds to brush it with a steel or brass scratch brush until the solder "takes" and adheres to the immersed surface.

Scientific Progress.

California Pictographs and Hieroglyphics.

MRS. THEODORE H. HITTLE, S. F., Cal., in *Science*.

The study and investigation of the works of the earliest inhabitants of a country is now a science in itself, and is receiving more and more attention in all parts of the world.

Too little has heretofore been done in California, Alaska, Nevada, and Arizona to investigate, gather up and preserve the relics and works of the prehistoric races which inhabited these western territories, and, as there is now but little left, that little should without delay be carefully sought out and put in such shape as to remain a permanent possession. Of much, on account of our own carelessness, we have been despoiled, and much that yet remains has been more or less defaced and injured.

Government as well as scientific societies should look to the preservation of what remains of the structures, tools, utensils and weapons of the aborigines, and by all means endeavor to gather together and preserve by photographs the cipher writings which are yet to be found, and which, year after year, by the corroding hand of time and the more destructive hand of ruthless vandalism, are becoming more and more defaced and ruined.

The cipher writings yet to be found from Alaska to Arizona, if carefully gathered and studied, might enable us to learn many very important facts concerning the customs of the redskins and their early history.

In the Sierra Nevada mountains, near the so-called Summit Soda springs, about 14 miles south of Donner lake and at an elevation of about 6000 feet above the level of the ocean, the attention of tourists is attracted by numerous inscriptions incised in the rocks.

The most prominent, and the most inviting of attention of these, are those cut in the granite rocks, about 100 feet high, which stand nearly isolated on the right and on the left of the headwaters of the north fork of the American river.

The stream there is almost a little torrent and dashes over the rocks in cascades, and from there it plunges into and through a mountain gorge toward the lower level far below.

To a person standing near the fountain-head of the river, on the rocks against which it chafes, and which it is gradually but surely wearing away, and who takes note and truly appreciates the grandeur of the scenery, there comes a feeling of awe and reverence. It elevates the soul and calls forth a spirit akin to religious worship.

It was here in this sublime region that an unknown people left pictographs on the rocks pertaining doubtless to their history and religion. The seasons of centuries since then have come and gone; the snows of uncounted winters have covered them; succeeding springs and summers unnumbered have decked the mountains with yearly verdure, and the river has been rushing on and on ad cutting its bed deeper and deeper. All this we know; but we know nothing of those who wrote these ciphers on the monumental rocks. They have passed away.

Only with the help of science and long study and comparison can we hope to gain an inkling of the meaning these ciphers were intended to convey, and add, perhaps, some important facts to the ancient history of California—a subject now so full of interest and becoming daily of more and more interest to the world.

According to the Report of the Bureau of Ethnology at Washington, pictographs of the North American Indians are found at Santa Barbara and San Diego in California and in Nevada, Arizona, Oregon, Idaho and Utah.

In Nevada, great numbers of incised characters of various kinds are found on the rocks flanking Walker river. These are waving lines, rings and what appear to be vegetable, animal and human forms. Among the copies of pictographs obtained in various portions of the Northwestern States and Territories by Mr. Gilbert, one kind is referred to as being on a block of basalt at Reveille, Nev., and is mentioned as Shiouma or Mosquis.

This suggestion is based upon the general resemblance to drawings found in Arizona, and known to have been made by Mosquis Indians.

In Oregon, numerous boulders and rock escarpments at and near The Dalles of the Columbia river are covered with incised or

pecked pictographs. Human figures occur but other forms predominate. From Lieut. J. H. Simpson's Topographical Bureau Report we take the following: "At the Rio de Zuni, in 1849, we met Mr. Lewis, who had been a trader among the Navajos, and, according to his statement, had seen inscriptions on a rock on his travels to and fro. He offered to guide us. He led us to a low mound. We went up and found inscriptions of interest, if not of value, and of them some dating so far back as 1606. The rock is since mentioned as Inscription Rock."

Mr. G. K. Gilbert discovered etchings at Oakley Springs, eastern Arizona, in 1878, relative to which he remarks that an Orabi chief explained them to him and said that the Mosquis make excursions to a locality on the Colorado Chiquito to get salt. On their return they stop at Oakley Springs and each Indian makes a picture on the rock. Each Indian draws his crest or totem, the symbol of his genus. He draws it once, and once only on a visit.

From Alaska to Arizona many inscriptions on rocks are found. Of some of them photographs have been taken. But so far as we know, none are as extensive or of such variety and of so ancient a date as those situated near the source of the American river.

These pictographs seemingly resemble and are written in much the same way as the Chinese ciphers, where each figure is a word and has a full meaning, and seemingly they should be read from right to left.

The Estimation of Manganese in Ores.

A new method for estimating the manganese in ores has been discovered by Mr. A. H. Low. The length of time occupied by the entire analysis is said to be never greater than 20 minutes, and none of the usual constituents of ores interfere with the working of the process. The following solutions should be prepared: (1) A standardized solution of potassium permanganate, approximately one-tenth normal. (2) A solution of oxalic acid containing 11.46 grammes of $C^2H^2O^2 \cdot 2H^2O$ per liter; the exact strength of this solution is to be determined by titrating with the permanganate in the presence of hot dilute sulphuric acid in the usual way, and then its value calculated on the basis that $C^2H^2O^2 \cdot 2H^2O = Mn$; it will be found that 1 cubic centimeter will be equal to 0.005 gram of Mn or about 1 per cent when 0.5 gram of ore is taken for analysis. (3) A saturated solution of bromine in cold water, an excess of bromine in the bottle; under the conditions to be described 25 cubic centimeters of this solution will precipitate about 35 per cent of manganese. In carrying out the analysis 0.5 gramme of the ore is treated in a 16 oz flask with whatever acids are necessary to decompose it, usually 5 to 10 cubic centimeters of hydrochloric acid or aqua regia are sufficient. After all traces of free acid have been removed by heat, the solution is diluted with 75 cubic centimeters of hot water and an excess of zinc oxide added. The solution is boiled to effect complete neutralization of the acid. An excess of the bromine solution is then added; about 25 cubic centimeters is usually sufficient, and never more than 50 cubic centimeters should be added. The solution is boiled for a moment or two until the excess of bromine is expelled, and an excess of zinc oxide should all the time be observed in the bottom of the flask. When all the red fumes have disappeared the solution is filtered on a paper 5 inches in diameter and the flask and precipitate washed several times with hot water. The precipitate and filter are replaced in the flask and about 50 cubic centimeters of dilute (1.9) sulphuric acid added. Into this mixture is run from a burette an excess of the oxalic acid solution, and the mixture is heated to boiling; afterward more oxalic acid is added if necessary, so as to complete the solution of the precipitate. After diluting the solution with hot water the excess of oxalic acid titrated with the permanganate solution. The amount of oxalic acid actually consumed by the MnO^2 is thus arrived at and the percentage of manganese can then be calculated.—*American Manufacturer*.

PURIFICATION OF MERCURY.—Redistilled mercury, intended for exact measurements (the construction of standard barometers, resistances, etc.) is further purified at the German Physico-Technical Institute by electro-deposition from a solution of the nitrate obtained by the action of pure nitric acid on an excess of the metal. The density of the current employed, is at the anode .003 and at the cathode .012 ampere per square centimeter.

EXPERIMENTS in propelling canal boats by electricity are to be made on the New York State canals, the Legislature having appropriated \$12,000 for that purpose.

Metallurgy and Ores.

**SELBY
SMELTING and LEAD CO.,**
416 Montgomery St., San Francisco

**GOLD AND SILVER REFINERY
And Assay Office.**

Highest Prices Paid for Gold, Silver and
Lead Ores and Sulphurets.

— MANUFACTURERS OF —
**BLUESTONE,
LEAD PIPE,
SHEET LEAD,
SHOT, Etc., Etc.**
ALSO MANUFACTURERS OF
Standard Shot-Gun Cartridges.
Under Chamberlain Patent.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

**ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,**

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

68 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scoop-
ers, etc., including, also, a full stock of
Chemicals.
Having been engaged in furnishing these sup-
plies since the first discovery of mines on the
Pacific Coast, we feel confident from our experi-
ence we can well suit the demand for these
goods, both as to quality and price.
Agents of the **Denver Fire Clay Co.** and
for the **Morgan Crucible Co., Battersea,
England.** Also for **E. G. Denniston's Silver
Plated Amalgam Plates.** The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of Silver guaranteed. Orders taken at his lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

JOHN TAYLOR & CO.

BOOKS ON ASSAYING.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working
precious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt. It
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assays; Examples of Dressing; The Melting in
Crucibles; Scoffication; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Cupel Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.
The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1889. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

**Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.**

SECOND EDITION—JUST OUT.
Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion,
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhart's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel
and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.
One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

MINING AND SCIENTIFIC PRESS.
The Leading Mining Journal in America.
Established 1880. Latest Discoveries in
Science and Improvements in Mining and
Mechanic Arts illustrated or described. A Stand-
ard Illustrated Weekly published at \$3 a year by DEWEY
PUBLISHING CO., 220 Market St., San Francisco, Cal.

G. W. PENNINGTON & SONS, STEEL WORKS.

MANUFACTURERS OF

**Best Refined Cast Tool Steel, Machinery and Hammer Steel,
Steel Piston Rods, Shear Blades, Lathe Spindles, and all kinds of Steel
Forgings Made to Order.**

**REFINED BAR STEEL IN OCTAGON, ROUND, SQUARE OR FLAT, MADE IN SIZES
AND LENGTHS TO ORDER.**

Miners' Drill Steel, Picks, Crowbars, Sledges, Hammers, Etc.
Obtainable in Size and Length Manufactured to Order. N. B.—Drill Steel, an Length
from one to thirty feet.

OFFICE AND WORKS:

218 and 220 FOLSOM STREET, - - SAN FRANCISCO, CAL.

STAMP MILLS.

FRANCIS SMITH & CO.,

MANUFACTURER OF

SHEET IRON & STEEL PIPE

FOR TOWN WATER WORKS.

Hydraulic, Irrigation and Power Plants, Well Pipe, Etc., all sizes.

NO. 130 BEALE STREET, SAN FRANCISCO, CAL.

Iron sent, punched and formed, for making pipe on ground where required. All kinds of Tools supplied for
making Pipe. Estimates given when required. Also prepared for coating all
sizes of Pipes with a composition of Coal Tar and Asphaltum.

Professional.

**A. LEONARD,
Mining Engineer.**
Graduate of Laval & McGill.

Head Office, QUEBEC. Branch Office, SHERRBROOKE.
Branch office, MONTREAL, 17, Place d'Armes Hill.

**STEPHEN H. EMMENS,
Consulting Engineer and Chemist,**
Youngwood, Westmorland County, Pa.
SPECIALTIES: Nickel, Tin, Dry Placer Develop-
ment, Treatment of Refractory Ores, Electric Heating
and Smelting.

C. A. OGDEN, W. N. JARU.

**JEHU & OGDEN,
Chemical Laboratory and Assay Office.**
(Formerly Evans' Assay Office.)
628 MONTGOMERY ST., San Francisco.
ROOMS 46 and 47 MONTGOMERY BLOCK.
Ore Assays, Analyses of Minerals, Waters, all Tech-
nical products, etc., made.
Lessons given in Assaying and Chemistry.

**School of Practical, Civil, Mechanical,
Electrical and Mining Engineering,
Surveying, Architecture, Drawing and Assaying,
728 MARKET ST., SAN FRANCISCO, CAL.**
Open all year.
A. VAN DER NAILLEN, President.

Assaying of Ores, \$25; Bullion and Chlorination Assay,
\$25; Blowpipe Assay, \$10. Full Course of Assaying, \$50.
ESTABLISHED 1864. Send for Circular.

Constantly on hand a full assortment of Manila Rope
also Rope, Duplex Rope, Tarred Manila Rope, Hay Rope
Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.
611 & 613 Front St., San Francisco, Cal.

Electricity.

Electric Haulage in Coal Mines.

The problem of economic haulage in mines has lately received considerable attention from mine-owners, who have found the expense involved in haulage alone much greater than in their opinion it should be. The mule has had his day as the principal factor in the haulage question, and the cable is under test, with results more or less satisfactory. The electric locomotive for mine work is comparatively a new-comer in the haulage field, but it has already acquired considerable prestige and bids fair to supersede both the mule and rope haulage.

An excellent example of the work done by the electric locomotive in coal-mining is shown at the Rock Springs coal mine, at Rock Springs, Wyoming. This plant was installed by the mining department of the Northwest General Electric Company, and is described in the *Electrical Review*.

About a mile from the mouth of the mine the power station, containing a dynamo of 80-horse power driven by a steam engine, is located. Current from this is delivered at a pressure of 550 volts, which allows of a drop of about ten per cent between the powerhouse and the mine.

The feed or supply wire is No. 000 hard drawn bare copper, making a complete metallic circuit. The trolley line is furnished with a circuit-breaker about 30 feet from the mine mouth, so that the current may be cut off from the mine when the locomotive is employed for switching purposes outside.

The locomotive used is of the G. L. M. General Electric Company type, of 30 inch gauge, 60-horse power. Its usual speed in this instance is about eight miles an hour. The cars used are of the ordinary coal-mine type, weighing each, when filled, about 3000 pounds; when empty, about 1000 pounds.

The economy attained by the use of this locomotive is strikingly illustrated by the fact that by its aid 30 cars were run from the loading point to the end of the track, a distance of about 6000 feet, there dumped and returned to the mine in 20 minutes. On another occasion the locomotive drew after it 30 loaded cars and pushed ahead 16 others from end to end of the road without difficulty. The track is built of 35-pound T rail, and has several switches and spurs necessary to the rapid handling of the cars.

It is not inappropos here to quote from a letter from an expert, giving an account of contact with the bare wire and the results thereof:

"Several men have been shocked since our plant began operating, but the effect is only momentary and they only laugh at it. The result has simply been to remove all fear they had of it. As I stated in my letter, this is a very dry mine, and so the only way one can get shocked is to stand on a rail and touch the wire. I have been shocked several times myself while handling the locomotive, through thoughtlessness. The other day a balky mule ran right into the wire with his head. He was knocked down. He got up and ran into it again three times, and was dropped in every instance. After that he was simply turned around and walked off to his work. I ought to remark that the shock does not knock a man down or burn him. The only description I can give of its effect, from personal experience, is a tingling sensation lasting, in the heaviest shock I received, not more than one or two minutes afterward in the hand that made contact."

This last is a fact which should reassure mine-owners who have any fears of danger from contact with the trolley wire. The element of danger once recognized as entirely absent, the electric locomotive can compete on equal grounds with any other system of haulage, with many points in its favor which cannot be urged by its competitors. We expect to see its adoption become general, both on account of the economy of its operation as well as its convenience of manipulation.

Electric Wiring and Insurance.

The fire losses during the last three months in the insurance world have been quite heavy, amounting to about \$45,000,000. If the proportion were continued, this would mean a yearly destruction by fire of about \$180,000,000 of property. This enormous loss is naturally worrying the insurance companies, and they are keenly on the lookout for new and unexpected causes. The fact that this is an increase over last year's losses makes them believe that some very recent cause is at the bottom of it all, and forthwith appears the following report from New York city:

"A leading insurance man says that for the six months ended December 31 insur-

ance companies of this city received in premiums about \$3,000,000, and paid out in losses about \$5,000,000. The losses came principally from electric wires and lights in buildings. For this reason the insurance companies have raised the insurance rates from two cents to 25 cents on each \$100."

This rather astounding statement naturally leads us to inquire into its authenticity, and another report comes, as it were, to counteract the bad effect thus produced, which reads:

"Fire and Water says returns from 76 cities for 1892 show that there were 1230 fires. Of the losses due to these fires only one-fourth of one per cent was caused by electric wires. Of all other causes that of these wires was the smallest."

It is obvious that these opinions differ most materially, and as the subject is one about which no definite conclusion can be reached, opinions will continue to differ. There, however, seems to be a decided impression among prominent officials in insurance circles, to the effect that electric installations increase the hazard on fire risks. It is a difficult matter to get down to the root of the question in this abstract subject, wherein statistics are the only means of furnishing any information, and even their application is entirely theoretical. But let us take a few facts, which in a statistical way are about as authentic as any others that can be obtained.

After a collective canvass of several prominent insurance officials, the following figures, which may be liable to fluctuation, were obtained. It is estimated that about 75 per cent of the fire losses are due to "causes unknown." Since the extensive installation of electric light and power plants, it is imagined that about 25 per cent of the losses have as their origin imperfect wiring, and of this 25 per cent two in 30 have been traced directly and positively to defective electrical construction. By simple calculation we find that the proportion of fires caused undoubtedly by defective electrical construction is $1\frac{1}{4}$ per cent. Thus we see the apple of discord is imperfect wiring, and as soon as this factor is eliminated the risks attending electric light and power installations will be practically nil. It should, however, be stated that the quality of wiring work is improving daily.

The insurance companies are, however, "reaping the whirlwind" from the policies on plants which were wired three or four years ago by incompetent men, for they claim fires are continually resulting from imperfect insulation and bad joints. The companies now refuse to grant policies unless all rules laid down for perfect wiring are rigidly complied with, and it follows as the night the day that with better insulation and more careful work electrical installations will be recognized as the safe system, and will be looked upon with great favor by the insurance men.

MM. LAGRANGE AND PAUL HOHO, who for some little time past have been investigating the phenomenon of the luminous sheath which surrounds a fine wire when used as the negative electrode in an electrolyte, recently made a communication to the Comptes Rendus with regard to an interesting utilization of this fact. These investigators found that a piece of iron ten centimetres long and one centimetre in diameter could be heated by the proper arrangement of non-conducting screens, in alternate centimetre-long sections, the heated sections fusing while the cool sections were still quite cold. So rapid was the heating that a rod of iron could be made white hot at the surface before the interior was affected, so that by suddenly making and breaking an electric circuit, the surface of a piece of iron could be suddenly heated up and then quenched in the electrolyte. The application of this process to the tempering of springs is obvious, and one may perhaps be permitted to see in it the germs of a new method of giving a hard surface to an armor plate.

PURIFICATION OF SUGAR.—A short article in *L'Electricien*, taken from *Genie Civil*, refers to the possibilities of the application of electrolysis to the purification of sugar. It speaks of the Fabrig process, which consists in bleaching the sugar by means of ozone produced by passing electric discharges through the sugar. In recent experiments made in Hoym, Germany, the rebeated juices are subjected for eight or ten minutes to electrolysis between zinc electrodes (35 to 40 amperes, 4 to 5 volts), when a thick viscous deposit will precipitate at the positive electrode, which gradually falls to the bottom and which is separated from the liquid by filtration; this deposit is one-third oxide of zinc; the juices and the sugar are absolutely free from this. Regarding the possible inversion of the sugar by the cur-

rent, as has been suggested, he thinks there is no reason to fear it, judging from the experiments of Mr. Groinigg, which have been very successful.

Useful Information.

A Short History of Stoves.

The cook stove, as well as that for heating, is in its comparative perfection a matter of the past 50 years. To those who can go back to that time, the expedients by which our grandmothers brought their edibles to such a state that they were even digestible would be a marvel to those who never had the fortune to have the experience of genuine camp life. The tin-baker and the bake-kettle have passed away, and through many evolutions, the modern range, with hot-water attachments and the folding gas stove, have left little to be desired. The stove is an invention, however, of antiquity, traces of it having been found in the historical annals of China and Japan, and fragments unmistakably pointing to such an article were found in the ruins of Pompeii.

Large, clumsy stoves were made at an early day in Holland, Germany and England, and to this day in those countries the same forms and styles to a considerable extent are used. In Italy, at the present time, in the small towns, an iron box resting on the ground, with side handles and rude holes cut for draught, is used. In some cases even iron is not employed, but in its place terra cotta and stone are substituted.

The stove in America is chief in its civilizing tendencies. To get a good stove in the country districts is the first thought of a married couple, and the advantages of every available pattern are fully discussed in advance.

The American stove dates back to 1742, and for it credit is due to the busy, level brain of Benjamin Franklin. It was then the open front, or a departure from the ordinary fireplace. This stove was introduced into England, and everywhere the "Franklin," as applied to its peculiar form, is known to-day. It held sway long into the present century, and then inventions and improvements rapidly followed one another, beginning with the ordinary air-tight (over which *pater familias* spent many anxious hours debating whether it added to the bills of the physician) down through every kind of draughts, all sorts of dampers, beating stoves in which the fire would not go out, all sorts of gas stoves, until now they essay at electrical heating.—Hardware.

To Prevent White Efflorescence on Brick Walls.

The white efflorescence which so often disfigures our otherwise handsome brick buildings and gives to them an appearance of dilapidation not justified by their age, is said to be due to the presence of lime in the clay from which the bricks are made. Numerous remedies have been suggested, generally consisting of a kind of paint to be applied after the bricks are laid in the wall, and while generally successful in so far as they prevent the exudation of the discolored element, do not preserve the original appearance of the wall. *Thouindustrie-Zeitung* says, that where lime is the cause of the efflorescence it can be entirely prevented by dipping the bricks before burning into dilute acid. The strength of the acid should be determined by the amount of lime present in the clay, the greater the amount of lime the more dilute the acid. For ordinary clay, it says a solution composed of 40 quarts of water to one of hydrochloric acid is the best for the purpose, and the quantity sufficient for dipping 500 bricks, when the solution should be renewed. The bricks having been dipped and thoroughly dried in the sun are dipped and dried again just before burning. The operation only adds 12 cents a thousand to the cost of the bricks in Germany, and while the added cost would be somewhat greater in this country, the idea would seem to be worthy of adoption by our brick-makers, who could command a moderate increase on the price of their material by guaranteeing the absence of the white coating.—Northwestern Architect.

The New Ocean Voyager.

The Campania was built by the Fairfield Co. for the Cunard line, and is now the largest steamship in the world. On her trial trip, in shallow water, she ran over 22½ knots per hour, and on a longer run she approached 23 knots, or 26½ statute miles an hour. The Campania is 620 feet long by 65 feet 3 inches broad and 43 feet deep.

The following figures show the relative

sizes of some of the big ships which have crossed the ocean:

	Campania.	Paris.	Teutonic.	Great Eastern.
Length.....	620	527	565	680
Beam.....	65	63	57.6	82
Draught.....	32	29	26	31
Horse power.....	30,000	20,100	17,000	7,650
Tonnage.....	17,000	10,500	9,686	20,000

New Method of Blasting Coal.

In using the Plom and d'Andrimont excavator for forming a chamber at the end of shot-boles, an ordinary shot-hole is first drilled in rock or coal; when in the latter, by an ingenious modification of the Lisbet hand-drill, and then the excavator or chambering tool is introduced and rotated by the ratcheted-lever or handle, according as the coal presents greater or less resistance. By bolidging, from time to time, the nut of the screwed end of the shank the latter is moved forward so as to cause two blades to open out and excavate a chamber, which may be as much as a foot in diameter. The coal dust produced by the boring is withdrawn by the coarse, screw of the shank. When the chamber is formed, the nut is turned in the opposite direction, an action which causes the blades to collapse, so that the tool may be withdrawn from the hole. The charging, which should be by gunpowder for coal, is effected by a brass or copper tube, having longitudinal slots at the end. The tamping consists of a wooden plug carrying the ignition fuse and held in place by clay filling. As the action of the gases due to the explosion is exerted in a direction perpendicular to the face, the roof and floor are unaffected and the coal is detached in large blocks, which are not thrown forward but only pushed outward for a few inches. The proportion of large coal is therefore increased, while a considerable saving of labor is effected. This appliance is used at the Hasard Colliery, near Liege, and has been favorably reported upon by the managers of several collieries in Germany, including the Frederika Tiefbau, the Carolinen and Gluck, the Eschweiler, Prinz von Preussen, Konig-Ludwig and Frederick der Grosse.—Colliery Guardian.

Turkish Baths and Heart Disease.

We see it so often stated that those who have the slightest trace of heart disease should never take Turkish baths that we welcome a word on this subject from the *London Lancet*, which says: "It would be idle to say that the Turkish bath should never be employed in any case where there is any disease of the heart, for attested records show that patients suffering from well-marked valvular disease have in many cases derived considerable benefit from its use, and the records of more than one lunatic asylum show that the influence of the Turkish bath in varied forms of mental disorders and cerebral disease, has been most beneficial. In fact, in dropsy from heart disease, as in dropsy from kidney disease, in albuminuria and mania, the Turkish bath has proved a very potent agent. So that it would be injudicious to lay down as a canon, that either heart disease or cerebral disorder contra-indicate the bath; they may prove direct indications for it. But they certainly afford grounds for care and reason for insisting on close supervision and vigilant watching. The therapeutical effects of the Turkish bath deserve the continued study of the profession; it has proved itself, as we anticipated, a potent therapeutical agent. Sir John Fife, Dr. Barter, Dr. Lockhart Robertson and others have, on a large scale, applied most usefully this invaluable introduction of Mr. Urquhart, to whom a great debt is due for impelling the creation of these baths in London." This is exactly our own experience, but of course, as a matter of caution, patients with weak hearts should be watched and not allowed to remain too long in the hot room of the bath, nor should they enter when wearied and excited, nor when the bath is so full they cannot have instant attention when wanted.

NEW INSULATING COMPOUND.—Micanite, says *Electricity*, is a new material, lately brought into the market, and reported to possess very high insulating properties. It consists of ground mica and shellac mixed together, and rolled or pressed between plates to a uniform thickness. Both mica and shellac, as is well known, are materials of very high insulating capacity, and the advantage of micanite seems to be that it can be obtained in almost any shape, such as rings, washers, tubes, plates, etc. In addition to its high insulating capacity, it can stand a great deal of mechanical wear and tear, and a very high temperature without breaking down in insulation.

Earthquakes Foretold by Animals.

An Italian writer on the dreadful catastrophe which occurred on the island of Ischia, mentions those prognostications of an earthquake which are derived from animals. They were observed in every place where the shocks were such as to be generally perceptible.

Some minutes before they were felt, the oxen and cows began to bellow, the sheep and goats bleated, and, rushing in confusion one on the other, tried to break the wicker-work of the folds. The dogs howled, the geese and fowls were alarmed and made much noise; the horses which were fastened in the stalls were greatly agitated, leaped up and down and tried to break the halters with which they were attached to the mangers; those on the road stopped suddenly and snorted in a very strange way. The cats were very much frightened and tried to conceal themselves, or their hair bristled up wildly. Rabbits and moles were seen to leave their holes; birds rose as if scared from the places on which they had alighted, and fish left the bottom of the sea and approached the shores, where at some places great numbers of them were taken. Even ants and reptiles abandoned, in clear daylight, their subterranean holes in great disorder many hours before the shocks were felt. The dogs, a few minutes before the first shock took place, awoke their sleeping masters by barking and pulling them, as if they wished to warn them of the impending danger, and several persons were thus enabled to save themselves.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

Mining Superintendent

I am desirous of obtaining a position as Mining Superintendent. I am a graduate of the Columbia School of Mines, and have had 15 years practical experience as superintendent of mines and mill's. Special experience as expert in concentration and amalgamation. W. J. ADAMS, Room 15, No. 132 California St., S. F.

Voltaic Mineral Rods.

Certificate of Copartnership.

WE CERTIFY THAT WE CONSTITUTE A PARTNERSHIP transacting business in this State. Its principal place of business is San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are Samuel B. Connor, residing at San Francisco, California, Andrew S. Grant, residing at San Francisco, California. SAMUEL B. CONNOR [SEAL] ANDREW S. GRANT.

July 12, 1890.

State of California, City and County of San Francisco—ss.: On this 12th day of July, in the year one thousand eight hundred and ninety, before me, George T. Knox, a Notary Public in and for said City and County, duly commissioned and sworn, personally appeared Samuel B. Connor and Andrew S. Grant, known to me to be the persons described in, whose names are subscribed to, and who executed the within and annexed instrument, and they acknowledged to me that they executed the same.

In witness whereof, I have hereunto set my hand and affixed my Official Seal, the day and year in this Certificate first above written.

[Notarial Seal]

GEORGE T. KNOX, Notary Public.

I, M. C. HALEY, County Clerk of the City and County of San Francisco, State of California, and ex-officio Clerk of the Superior Court in and for said City and County, hereby certify the foregoing to be a full, true and correct copy of the original Certificate of Copartnership of Samuel B. Connor and Andrew S. Grant, filed in my office on the 12th day of July, A. D. 1890.

Attest my hand and seal of said Court, this 20th day of April, A. D. 1893.

M. C. HALEY, Clerk.

By Wm. H. Lyman, Deputy Clerk.

[Seal of Superior Court.]

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

KEYSTONE.—Amador Ledger, May 19: Superintendent Hale of the Keystones, Amador City, has been prospecting in a crosscut with a diamond drill. He has penetrated the greenstone about 80 feet, and it is proposed to go in 400 feet, taking out a core a little more than one inch in diameter. The drill is run with a water-wheel and is handled by two men. A Huntington mill has been added to the Keystone plant for the purpose of grinding the soft rock which is now being encountered. This machine is supposed to do as much work as 15 stamps will do. Superintendent Myers of the Bunker Hill has had the water all taken out of the Mayflower shaft and is now repairing the tunnel, which runs from Rancheria creek and taps the shaft. The lessees of the mine are expected to visit the property in a few days. The Pioneer, in Plymouth district, is looking better than at any time since Dr. Boyson procured the property. A. B. Summers, who has been pushing the work forward as rapidly as possible, a few days ago encountered a ledge of blue ribbon-rock which is very rich. This is of the same character as that found in the old Pacific. The New London of Plymouth, which was the property of W. Hyde & Co., has been sold to the people to whom it was bonded five months ago. N. J. Colman, an old Chester and El Dorado mining man, has been placed in charge and is arranging to secure some of the machinery from the old Pacific, which is now being dismantled. The new concern expects to use water from the high-pressure pipes of Haywards & Hobart. C. D. Lane and Chas. Nickerson, formerly of Sutter Creek, went into El Dorado county Monday to view the Oro Fino mine, which Nickerson sold in Lane & Haywards. Superintendent Tregloan, of the South Spring Hill, Amador City, for some time has had men at work running a drift from the Talisman to the Median, which belongs to the South Spring Hill Company. Blaisdell & Company have bonded a piece of property on the Amador and Sutter Creek road, opposite the South Spring Hill, and will begin work on the property in a short time. D. C. Wickham, of the Baldwin mine at National, El Dorado county, was in town during the week renewing his acquaintance with a few of the old-timers whom he knew here in early fifties. John Delzell, who for some time was the millman at the Hadenburg mine, has accepted a position in the mill of the Shenandoah mine, six miles from Mokelumne Hill. H. Tripp, whose mine is located near the Mokelumne river bridge, is getting ready to put a pump in the lower tunnel and thoroughly prospect it. D. Gutmann and Ed. Lemer came up from San Francisco last Sunday evening and the following morning went to the Irma mine, Pioneer district, in which they are interested. Superintendent Parks, of the Kennedy, informed us Tuesday that he expected to open up the vein on the 1650-foot level during the week. The ledge in this 1750-foot level is looking better this week than ever. The Kennedy is a great mine. J. B. Francis was up at the Irma mine, in Pioneer district, this week, and says the prospects continue fine. In the lower drift, which runs from the 200-foot level, the ledge is two feet wide, and Mr. Francis believes the rock will yield \$100 per ton in free gold. Superintendent Fisher asked Mr. Francis to have an air pipe and a blower sent up, which was done to-day.

Calaveras.

SUSPENDED WORK.—Mountain Echo, May 20: Operations were suspended at the Utica and Stickles mines last Tuesday and Wednesday, pending the cleaning of the Utica Company's ditch and the laying of new pipe.

AT THE UTICA.—Calaveras Prospect, May 20: Work in the Utica mine has been mostly suspended during the week, pending changes in the works on account of the new water pipes. On Tuesday nearly all of the miners were put to work on the ditch cleaning it out and enlarging it so that it will carry all of the water required. Wednesday was pay-day and all of the men were laid off for the day. In a few days all the connections with the new water pipes will be made and everything will be running. * * * Twenty new Tulloch concentrators are to be put in the mill. There will be ample power now to run all of the works of both the Utica and Stickles mines and mills. The men were to commence work with the midnight shift Wednesday night.

TO RESUME WORK.—It is now confidently stated that the Calaveras Consolidated mine at Robinson's Ferry will start up on the 20th. All litigation has been settled in a manner satisfactory to all parties and highly honorable to the company. Quite a force of men will doubtless be put at work extracting ore and milling, as the mine is well opened. The working of this mine will be a great help to the little community about the Ferry and will encourage others to operate mines in that excellent mining section.

El Dorado.

GRAVEL.—El Dorado Republican, May 20: Messrs. Jungerman and Hall, two San Francisco parties who have bought the Gignac gravel mine at Texas Hill, have arrived in Placerville and taken charge of the property. They are building a flume about 600 feet long and have purchased a quantity of 11-inch pipe at the Blair mine, which will be moved upon the ground at once.

THE UTICA COMPANY'S MINE.—Calaveras Pros-

pect, May 20: A force of six or eight men who have been at work in the Stickles mine at Angels has been sent by the Utica Company to Shingle Springs, El Dorado county, to operate a mine owned by the company at that place. One of the machine drills was also shipped there. Nearly all of the men who went are old residents of the town. Charles Lillis goes in charge of the men.

Humboldt.

ORLEANS BAR.—Cor. Blue Lake Advocate, May 20: I found all the miners at work, as they have lots of water. There is talk of some new claims opening up this summer near Orleans and all the old mines will run for weeks yet; so we expect good times here this summer. No idle men can be found here now, everybody being at work.

COAL.—Messrs. George Harpst and Supt. Ed. Ellis of the Gold Bluff mine, reached Blue Lake Saturday from the former's ranch on Goodman prairie. Mr. Ellis made a critical inspection while there of the outcroppings of coal on the ranch and brought away a nice specimen, though through mistake he did not get the fine specimen he had laid aside to bring along. The ranch, which embraces 600 acres, extends along Mad river, following the course of the stream, a distance of a mile and a half, and almost all this distance there are outcroppings of what appears to be a real good quality of coal. There are very thin layers of slate in the lumps taken out just beneath the surface, but the coal burns finely, and even the trash coal, as Mr. Harpst terms it (crumbly of the big lumps), when scooped up and put upon the fire run together and form one solid cake, making an excellent fire and burning until almost entirely consumed. Mr. Harpst has known of these outcroppings since January, 1892, and the more he investigates the better pleased is he with the indications. The outcroppings are almost all low down, near the bed of the river, though upon the hill back of the stream are surface indications of what appears to be a vein of semi-lignite coal. Since the foregoing was written Mr. Harpst has sold this Goodman prairie ranch of 600 acres to Mr. E. M. Wheeler, who, for the past year or so, has occupied the Capt. Gear ranch, across the river. Mr. Wheeler removed to his new home this week. He thus gets most of the land on which this coal has been found.

Nevada.

RICH STRIKE.—Grass Valley Telegraph, May 17: For several weeks the Evening Star mine has been looking exceptionally well, but last night it really excelled itself by turning out some of the richest ore yet seen from the ledge. The Evening Star is on Dead Man's Flat, and used to be called the Seven-Thirty. Mr. Taylor, the superintendent, brought to town some ore from the mine to-day, and that ore was rich enough to necessitate its being placed in the bank. The rock is filled with gold, and comes from the 200 south drift. The rock in the entire ledge is looking firm, and a crushing will be had during the first part of next month. The company expect to crush about 300 tons of ore at that time. The mine is being most carefully and energetically worked, and all economy is shown everywhere around its surroundings.

ABOUT COMPLETED.—Grass Valley Telegraph, May 22: W. S. Rogers and T. F. Anderson, who have the contract for building the hoisting and pumping works at the Central North Star, have almost completed their labors. They moved the machinery and are putting it in place. Mr. Rogers informs us that the work at the Central North Star will be completed in about two weeks. The gentlemen also have the contract on the Osbourne Hill machinery, and that will be completed in a short time.

THE DIAMOND AND MAUD MULLER MINES.—Grass Valley Union, May 21: A promising prospect that no doubt will be a piece of paying property in the near future is the Maud Muller mine. This mine is situated in the Forest Springs mining district and is near the Norambagua mine. The shaft is down to the depth of 60 feet and the ledge of 18 inches in width is in the shaft. The mine is being worked by Grass Valley parties, and they will continue to sink the shaft for some distance yet before they start to drift. The rock in this section of the country has always been very good, but the veins are usually small. This mine has a ledge of average size, however, and some rock which was brought to this office yesterday looks to be of good quality and assays at \$50 a ton. The Diamond mine, situated about three miles south of town on the old Colfax road, has commenced operations. A steam hoisting plant and a steam pumping engine have been placed on the property and work is being pushed at a rapid rate. The machinery was brought to the mine and put up in 16 days—a remarkably big undertaking for so short a time. The shaft is down to a depth of 90 feet, and they expect to sink about 60 feet farther before they will strike the ledge. Men are kept at work both night and day, and eight men are employed. Mr. Thomas is sinking the shaft as rapidly as possible, and, when the ledge is found, it will no doubt be a large one.

Placer.

NEW MINING ENTERPRISE.—Nevada Transcript, May 22: Frank Bell, Wm. Ambrose, E. R. and J. W. Brown and a Nevada county party have formed themselves into a mining company to be known as the World's Fair Mining Company, W. R. Arthur, secretary. They will go to work immediately on ground below Col. Davis' Mammoth Bar mine on the Middle Fork of the American river.

DAMASCUS DOINGS.—Colfax Sentinel, May 20: D. J. Sullivan, superintendent of the Pioneer mine, has returned from a trip to the bay. Quartz mining has quite a boom at present in the Humboldt Canyon district. Ed Ford & Co., who have one of the best locations in the dis-

trict, are now pushing their work as fast as they can. They are grading for a ten-stamp mill and for a boarding-house. They intend to build a wagon road to connect with the Pioneer mine road. A drawback to their work is the lack of lumber, for which they must wait until the mills start up. Their ledge is a true fire-vein and shows plenty of free gold. Ford & Co. are pioneers in this district, and we wish them unbounded success, as they have labored under many difficulties to get their vein opened. J. Patrick, who has leased the Dorer mine, has quite a force of men at work, and is running day and night. This ore shows up well. The Pioneer mine is running full blast and paying dividends monthly. Take it all together, times will be lively in here this summer.

RIVER CLAIM.—Messrs. Gould and Jordan, who have a river claim on the North Fork of the American river about three miles south of Gold Run, are at present engaged in preparing the claim for summer work. Several men are at present engaged in working for them, and quite a number have been engaged to work as soon as the water in the river is low enough to permit. The claim is located where considerable mining was done in early days, but much ground that will pay yet remains to be worked. The Hidden Treasure at Sunny South is working a larger force of men than has been worked for years. The Sells Bros. at Bath are running a prospect tunnel on their quartz ledge. Crangas & Federer are taking out good pay from their gravel mine at Brushy near Forest Hill. Albrecht & Co. are driving ahead a tunnel in their mine, the Mammoth, which is situated adjoining the mine of Crangas & Federer. They have only a few hundred feet to run, when they will be in the same channel which is paying Crangas & Federer so well. They have now out a call for bids to run a part of the tunnel. P. Jourgensen of Sunny South, who has been working for some time at his mine in Duncan Canyon near Damascus, has struck rich pay. Mr. Jourgensen is an old miner, and has labored for a long time in his endeavor to strike pay. He has a large family and has struggled for a long time for the well-deserved good fortune that awaits him.

Plumas.

GOON STRIKE.—Plumas National Bulletin, May 20: While in Greenville we learned from Archie Warren that Angus Cameron had struck good pay in his drift mine at Oak Flat on the North Fork. For several years he has been driving a tunnel from the canyon to tap an ancient channel through Oak Flat between four and five miles in length. This tunnel is in 800 feet. A short time ago Mr. Cameron began an upraise from the tunnel, and, after proceeding about 20 feet, broke into a large channel of fine gravel, two carloads of which paid him \$9. His faith and energy have at last been rewarded, and his friends will be glad to learn of it. It certainly does seem as if he would be amply rewarded. Although the explorations have not been those which have been made, they show conclusively the existence of a rich channel for many miles through that section of country.

TAYLORVILLE NOTES.—Plumas National Bulletin, May 20: While in Taylorville, we learned that Jos. Gruss is running his mill on fair ore from the Genesee mine. A. Drsgovich is prosecuting work on Grizzly creek for a Chicago firm. J. S. McDonald will soon resume work on the Lodi quartz claim. The outlook for him is promising. John Sobrero is building an arastra to work ore from a development near the Genesee mine. Brandt & Knox have been taking out and crushing ore. W. S. Dean has started work at the old Peel mine. C. Morane is pining on Grizzly creek. J. C. Borden will work the Pilot. The tunnel is in 130 feet. He has but a short distance to run to tap the ledge whose croppings prospected well. R. W. and James Young own the Premium mine, and have been taking out ore. They begin crushing this week.

FROM SKOWHEGAN.—C. H. Clark came down from the Skowhegan mine, situated about 12 miles from Nelson Point between Nelson and Poplar creeks. He reports about four feet of snow in that section. He is operating his mine with prospects of good success. The claim is looking well. John Simpson is at work on a quartz ledge at the head of Squirrel creek. He discovered a vein last winter, which prospects well. The Pittsburgh Co. is at work in the channel of the West Elizabeth drift mine, and is taking out gravel. While on his way down, Mr. Clark met a California lion, a big fellow, about 30 feet away. He felt himself in close quarters for a few moments. He yelled at the lion. This caused the ferocious beast to face Mr. Clark, but the animal took fright and sprang off into the woods.

Siskiyou.

A NEW QUARTZ MILL.—Yreka Journal, May 24: A. G. Myers has purchased a new quartz mill and will put it up immediately in Quartz valley. It is known as the Crawford mill. It is something new in this part of the country. It is vastly different from the old stamp mill. This new mill arrived in Yreka the latter part of last week and was hauled away to its destination on Monday. While here we took a look at it as the different parts lay at the depot. It consists of a large circular iron frame about four feet in diameter, in which a number of large metal balls are rotated. The balls are 12 or 15 inches in diameter and weigh several hundred pounds. These, with several other parts, make up the mill. It will grind the quartz to an almost impalpable powder, and the gold particles alone, owing to their specific gravity, fall through the space into the mercury bath, while the tailings are carried upward by the force of the water and flow out over the top. It is claimed that this mill will grind the ore so finely that every particle of gold is set free and that it will save a greater percent of gold than any other process; also

that pyritic and other rebellious ores can be worked successfully by this method. Our mining interests are great in this country and the success of this mill will be of great interest to the miners and people in general.

GRAVEL.—The Greenhorn blue gravel mine had a little mishap last week. The pump, which has been doing good service for some time, gave out under the great pressure of work. Fifteen men have been at work on this mine for some time, turning out a quantity of "dust," but they will be laid off for a few days. The company telegraphed at once for another pump—larger and better than the old one. This mine is now an assured fact, as the amount of ground prospected reveals enough of good-paying gravel to last them for years. This should be gratifying not only to the projectors, but to many others, as it affords work for many and will put many a dollar in circulation. Mr. A. G. Myers has bought the Shores mine, in Quartz valley, and will immediately put up a Crawford mill. We understand that he paid \$3000 for this splendid property. So the good work goes on. The Red Hill mine, in Salmon River district, owned principally by Parker Bros., of Etna, is turning out well and is proving to be a very rich mine, so we are informed. Messrs. Murray & Co. have started up B. Lee's blue gravel mine at Greenhorn. They have put a pump in the shaft and now have it clear of water. This mine showed a splendid prospect, and no doubt it will be successfully worked.

Santa Clara.

RAN MOUNTAIN DISTRICT.—Saratoga Standard, May 19: On Tuesday last L. Radovich, a brother of Boz Radozich of this place, brought some specimens of manganese iron ore, cinnabar ore, magnesite and nickel ore to this office. Mr. Radovich has just arrived from the Red Mountain mining district on the borders of Santa Clara and Stanislaus counties, and says that things are flourishing in that section of the hills. In 1890 Mr. Radovich first discovered the mines from which these specimens are taken, and which are situated adjoining the old Grayson quicksilver mines. The mines are some 56 miles northeast of Saratoga and 36 miles southeast from Livermore on the other side of San Antonio valley. The specimen of manganese is taken from a location which consists of two veins, while croppings indicative of gold quartz bearing ledges run parallel with the same all through the location. The cinnabar ore specimen is from a location adjoining the foregoing, and will average as a prospect from croppings about 4 1/2 per cent. In these croppings the nickel ore was struck and shows a streak from two to seven inches wide. The magnesite comes from a mine situated two and one-half miles northwest of the manganese deposit, and is located in a place called Dikeman canyon. It is from one of the finest ledges ever discovered on the Pacific coast, being pure white, carrying a high percentage and being in a solid ledge, running for a distance of about two miles at an elevation of 3555 feet above sea level. There is plenty of wood and water in close proximity, and good roads to the mines, so that no difficulty is experienced in working them. There are parties now negotiating with Mr. Radovich for the shipping of all the manganese for the English market.

Trinity.

CLEAN-UP.—Trinity Journal, May 20: A clean-up made last week at the Hubbard mine in Trinity county after a 20 days' run realized \$6000 worth of gold. This mine is only one of many in this county, as will be thoroughly shown when water in sufficient quantity is brought out to the ground. Lack of water has caused many rich locations to lie idle and undeveloped, but the time will come, and soon, too, when such ground will be worked so as to yield a handsome profit.

THE same paper also contains the following regarding rich quartz discoveries recently made: We were shown some very rich quartz this week by Ezra Thomas, of Shasta county, who has been in this county for several weeks prospecting. The quartz was from a ledge about two and one-half feet wide which Mr. Thomas recently discovered in the Lower Trinity country. Mr. Thomas is a prospector of 20 years' experience and says that there are lots of good mines in this county which in time will be worked with big profit.

Tuolumne.

TUTTLETOWN NOTES.—Tuolumne Independent, May 20: The Cardwell mine is working night and day. The shaft is down over 100 feet. The company means business and we hope to hear the glad tidings soon that it has "struck it," and a bonanza, too! It is rumored that on the 20th the Calaveras Consolidated Gold Mining Company will resume operations at Robinson's Ferry. It has expended a large sum prospecting on its property and has at last found good ore. Its success will bring others to invest in mines in this vicinity.

ETNA.—Tuolumne Independent, May 20: The old Etna mine, which has for some time been idle, has again commenced work under the management of Clarence Hawley. There is at present considerable water in the mine and a pump is in operation night and day. As soon as all the water is taken from the mine a force of men will be put to work in the old tunnel which is now nearly 600 feet in length, and matters will be pushed until the owners either win or lose.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—Virginia Chronicle, May 20: 1500 level.—During the early part of this week we continued to extract ore and old fillings from the 10th to the 17th floors. Above the 17th floor we connected with the old workings from the 1400 level, which we worked some years ago, consequently we have no ore to ex-

tract upwards from our openings. Thirty-six miners working on ore extraction on this level have been laid off, and all ore extraction stopped, for the reason that the ore producing points have become exhausted. Prospecting work will be continued on this level with a small force of men. A south drift has been started at a favorable-looking point, 75 feet above the sill floor of this level. The drift starts in quartz formation of low assay value, and will be advanced in unexplored ground. 1650 level.—Have continued making necessary repairs to the drifts on the sill floor of this level and to extract some ore in working west from the old stopes, on the third floor, operating through the npraise, No. 6, carried up from the main northwest drift; also from the old stopes in working north from the crosscut run west from the northwest drift. A south drift started at the end of the crosscut run east from a point 60 feet up in the upraise which was started from the drift run west from these north workings, 27 feet above the sill floor of this level, has been advanced 32 feet; total length, 82 feet; in porphyry and some quartz. Have continued to extract some ore of fair quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. Shipments of ore to the Morgan mill have been stopped, as the present output of the mine does not exceed 25 tons per day. This limited amount of ore comes from the 1650 level openings. Have extracted during the week from all parts of the mine 397 cars of ore about 390 tons. Shipped to Morgan mill 559 1230-2000 tons of ore. Average assay value, per railroad car samples, \$26.01. The assay value per battery sample of all the ore worked at that mill during the week (655 tons), was \$22.11 per ton. Bullion shipped to Carson Mint, assay value \$12,341.19.

OPHEL.—Have continued the work of making the necessary repairs in the shaft, being joint work with the Mexican Company.

MEXICAN.—On the 1565 level—West crosscut No. 2 from the north drift from the east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 19 feet; total length, 238 feet, continuing in porphyry formation carrying clay separations.

UTAH.—340 level—West crosscut No. 3 from the north drift, from west crosscut No. 2, at a point 195 feet in from its mouth, has been extended 15 feet; total length, 166 feet; continuing in quartzite formation showing clay separations.

SILVER NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 10 feet, making the total length 347 feet; the face is in hard porphyry and low-grade ore. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 19 feet, making the total distance west of the joint shaft 3192 feet; the face is in porphyry and soft streaks of clay.

GOULD & CURRY.—200 level—West crosscut No. 5, started in northwest drift, 432 feet from main west drift, has been advanced 9 feet, through hard porphyry; total length, 480 feet.

SILVER NEVADA.—During the past week the men have been repairing the joint north drift and easing timbers.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level, has been advanced the past week 19 feet, making the total distance west of the shaft 3192 feet; the face is in porphyry with seams of soft clay.

ANDES.—On 420 level have suspended work in west crosscut from north drift from east crosscut No. 1 north. We have cleaned out and retimbered 40 feet of east crosscut No. 3 from main north drift.

BEST & BELCHER.—200 level—During the past week west crosscut No. 2, started in northwest drift, 230 feet from our south line, has been extended 20 feet, passing through quartz of no value; total length, 100 feet. 900 level—West crosscut No. 4, started in southwest drift 112 feet from west crosscut No. 3, has been extended 14 feet; total length, 70 feet; face in soft porphyry and clay.

HALE & NORCROSS.—1800 level—Advanced the npraise in west crosscut on our south boundary 12 feet; total height, 36 feet; the top of upraise continues in quartz yielding low assays. Main shaft.—Are retimbering above the 1300 level and continue making the necessary repairs in main incline.

CHOLLAR.—Are repairing and retimbering north drift, 850 level. The east crosscut near the south line, 930 level, is out 222 feet; face is in porphyry.

POROS.—The north drift from east crosscut, 850 level, is out 76 feet; face is in porphyry and seams of quartz. The south raise 80 feet south of Potocai winze, 930 level, is up 85 feet; formation in the top is porphyry and streaks of quartz. The north drift from east crosscut, 930 level, is out 78 feet; face is in five feet of fair-grade ore. The north raise, 1000 level, is up 90 feet on the slope; the top is in fair-grade ore. South raise, 1000 level, 20 feet south of top of raise from 1100 level is up 36 feet; top shows six feet of fair-grade ore. Have started a crosscut west on 1000 level, 120 feet south of top of raise from the 1100 level; face is in soft porphyry. Extracted and sent to mill the past week 487 tons and 750 pounds of ore from the 550, 930, 1000 and 1150 levels. Milled during the week 473 tons. On band at mill 100 tons and 1000 pounds. A average battery assays, \$24.90; average car sample assays, \$26.72. Shipped to the U. S. Mint, Carson, 422 pounds crude bullion.

EXCHEQUE.—At the Ward shaft are repairing the pump shaft and taking out old pipes below the 1600 level. The shaft is repaired to that point.

BULLION.—At the Ward shaft are repairing the pump shaft and taking out old pipes below the 1600 level. The shaft is repaired to that point.

ALPHA.—At the Ward shaft are repairing the pump shaft and taking out old pipes below the 1600 level. The shaft is repaired to that point.

WARD SHAFT.—Are repairing the shaft and taking out old pipes. Repairs are now completed to the 1600 level.

KENTUCK.—We continue to extract from two

to three tons of ore per day from the 160 level of the average value of \$30 per ton. On the 1100 level we are opening the sill floor and have extended the main drift south in ore of fair quality. The joint west crosscut near the Jack's south line has been extended 19 feet; total length, 50 feet. The face is in quartz and porphyry.

OCCIDENTAL.—Crosscut No. 6 from north drift, 750 level, has been advanced 17 feet; both crosscuts are in quartz and porphyry, with small seams of pay ore. The main south drift on 650 level has been extended 16 feet; total distance from No. 1 winze 302 feet; the face of the drift is in ore assaying about \$15 per ton. The Zedig drift, Sotro tunnel level, has been extended 14 feet; total length, 983 feet; the face is in porphyry with seams of quartz which show value by assay.

SILVER HILL.—The southeast drift on the 450 level has been advanced 5 feet during the past week, making the total distance from north line 118 feet; the face is in hard porphyry.

CON. NEW YORK.—The south drift from the bottom of the winze below the 650 level is in a distance of 49 feet; the face is in quartz, some of which gives fair assays. The west crosscut from southwest drift, 800 level, is in a distance of 28 feet; face is in quartz and porphyry.

Ferguson District.

PROSPECTS BRIGHT.—Pioche Record, May 18: The prospects for a good summer's work are bright indeed. Ferguson district may be relied on to materially help out this section of the country. John Viotti and partners, on their lease on the Jim Crow mine, are rushing the work and taking out some fine ore. They propose to make bay while the snn sbines. These day last was pay day for the Magnolia boys. The proceeds of the ore recently shipped to Salt Lake brought this about. As pay day has been passed for several months, quite a neat sum was distributed. The April Fool owners are constantly making discoveries which strengthen their faith in their properties. The latest is a discovery of extensive croppings immediately below the boarding-house, and within the April Fool side lines, which show free gold in abundance. Pieces knocked off for 75 feet along the course of this outcrop show free gold, and the owners are consequently elated. The force of men employed on the various properties will soon be increased. Frank Wilson is now at Pioche after mining and general supplies.

Pioche District.

PIOCHE CONSOLIDATED.—Record, May 18: Mr. John Longmaid, who was here for several weeks two months ago, looking over the various properties of the Pioche Con. Co., with a view of leasing a portion of them, writes Geo. C. Blanchard that Mr. John Claflin, for the company, declined to lease all or any considerable portion of the property, which refusal is based on the expectation that the railroad will soon be built here.

POORMAN MINE.—Messrs. Swindler and Lloyd have secured a year's extension of their lease on the Poorman mine, just east of town, from John C. Eames. Early in the week an important

strike was made in the claim through the east drift from the new working shaft. The ledge opened with a foot or more of high-grade chloride ore, the cbute pitching northwest and southwest. This, at a vertical depth of 150 feet, will give about 200 feet on the vein, with virgin ground clear to the surface. The development is made east of the wagon-road, where there are no signs of ledge croppings, and it is a strike of no little importance.

Yellow Pine District.

KEYSTONE.—Pioche Record, May 18: Latest mail advices from Yellow Pine state that the purchase of the Taylor half interest in the Keystone gold claim at \$40,000 had not yet been consummated. I. C. Blake, of Denver, is the party, it will be remembered, who was expected to make the purchase. The Keystone itself, though, is reported to show up large quantities of high-grade ore, only such as was necessary for development work having been extracted since last November. The working force has not been increased, but remains at three men. Mr. Blake is in that section personally inspecting the country which his railroad is to develop and may make the purchase before closing his business there. The principal excitement in that section is at Vanderbilt district, California, which the road has now about reached. At Good Springs everything is quiet and may continue so for a time. The weather, too, is becoming oppressively warm, and claims situated any distance from water will probably receive little attention until next fall.

Tuscarora District.

NAVAJO.—Times-Review, May 19: The stopes above the 150 and 350-foot levels continue to yield about as usual.

BELLE ISLE.—South intermediate drift above the 250-foot level extended 12 feet, through a large clay break which has cut off the ledge entirely. The stopes are looking about the same.

NORTH BELLE ISLE.—An upraise has been started from the south-line crosscut, south 300-foot level; progress 15 feet.

BRITISH COLUMBIA.

MORE FAVORABLE THAN EVER.—Nelson Miner, May 15: Scarcely a day goes by without adding something to the already large collection of satisfactory evidences of the vast extent and richness of the ore bodies of the entire central portion of British Columbia. That scarcely sufficient work has been done in many sections to determine the permanent nature of the mineral-bearing formations is quite true; but in every instance, when extensive development has been carried on, the results have been such as tend positively to set at rest any doubt as to the depth of the ore body. Some doubt was felt at first as to the existence of true fissures, but this has been cleared away long ago. The concensus of opinion as gathered from the best posted mining men in the country is that the fissure will be found in greater number as the developments of mining sections progress. In the meantime the extent of many of the deposits is so great as to render them even more valuable than an ordinary fissure. An example of this is to be found at Thunder Hill, where

MATHESON PATENT LOCK JOINT PIPE.

CUT SECTION.

A—Wrought Iron Ring Shrink on Pipe.
B—Bell End Pipe.
C—Body Pipe.
D—Lead Space, showing Patent Lock Joint.
E—Lead Space.

We take pleasure in calling the attention of Hydraulic Engineers and all users of Iron Pipe that we are agents for the "MATHESON LOCK JOINT LAP-WELDED PIPE," and are prepared to furnish same from stock or directly from the mills.

This pipe is of Wrought Iron and is adapted for Water Main, Gas Main, Sewer Pipe, Etc. External Diameter of either Standard Wrought Iron Pipe or Tubing can be furnished, and of any desired weight or gauge, in connection with the Matheeson Patent Lock Joint.

THE ADVANTAGES OF THIS PIPE ARE:

- SIMPLICITY IN CONSTRUCTION.**—Permitting handling without the aid of skilled labor.
- A RELIABLE JOINT.**—Whether used on light or heavy tubing.
- A SAVING IN COST** of transportation as compared with any other style of wrought or cast iron pipe.
- A SINGLE CONNECTION AT EACH JOINT.** where other kinds have a double one.

Water Gates, Hydrants, Stand Pipes and all Necessary Tools and Fittings for Complete Waterworks. Specifications furnished.

IRRIGATION PLANTS OF ALL KINDS,
INCLUDING HYDRAULIC RIVETED AND IRON PIPE, CAST IRON AND SCREWED JOINT PIPE AND FITTINGS.

WE ARE AGENTS ALSO FOR

BALL AUTOMATIC STEAM ENGINES (Pacific Coast),

HEINE PATENT SAFETY BOILERS,

IRON AND STEEL FLUMING,

DAVIDSON IMPROVED STEAM PUMPS.

JOHN H. MCGOWAN'S DUPLEX PUMPS,

BALDWINVILLE CENTRIFUGAL PUMPS,

ETC., ETC., SEND FOR CIRCULARS.

RISDON IRON WORKS.

SAN FRANCISCO, CAL.

the entire mountain is one large ore body, and the ore is taken out in benches like quarrying building stone. One thing which has rendered many old miners doubtful as to the lasting quality of the various finds is the fact that many of the ordinary conditions in this country were found to be quite different from what they had been accustomed to on the other side. To one who has been long familiar with the galenas of Colorado or Utah, the British Columbia galenas are little short of marvelous. In those places the ordinary large cube galena will run from 5 to 40 ounces in silver, seldom much higher, while the steel and spangle galenas are usually an average of 50 per cent higher value. What wonder, then, that the old-timer should shake his head doubtfully at an almost exactly opposite state of affairs, and be for a time unwilling to believe that such high-grade large cube galena could be other than isolated cases of shallow deposits. But even the most skeptical have been forced to change their opinion in face of a widening range of discoveries and added depth of development. The same is true of many other classes of ores common to this section, and, as outside capital is now awakened to these facts, it is impossible to foresee any reason why the predictions of those who know this country best should not be realized, and these predictions are that the mining interest of this region is a lusty infant destined to rapidly grow to giant strength.

UTAH.

THE OGDEN SMELTER—Salt Lake Mining Journal, May 20: J. A. Shettle, promoter and manager of the Ogden smelter enterprise, is in the city. He states that everything is progressing favorably and work will be commenced on the buildings in a short time. The plant will not be a smelter, as is the general impression, but a leaching mill. The machinery will be of the latest, with all the latest improvements, being automatic in character, so that a great saving will be made in running expenses. The capacity will be from 100 to 150 tons per day, and it is expected that most of the ore to supply the plant will come from the west and north. Mr. Shettle says representatives of Colorado capitalists are at Ogden, with a view to locating a large smelter there.

BINGHAM—A. L. Heaton, who, with Brewer & Moore, is operating the No. 10 mine at Bingham, says the shaft is now down 200 feet, and they have encountered some ore running from 25 to 30 ounces silver and 25 per cent lead. In 15 or 20 feet more they will have plenty of ore, as they will encounter the vein of the Chicago, an adjacent claim, on its dip. This vein is very rich, having produced \$500 ore in the past. The No. 10 lies just below the Brooklyn. A shipment will be made soon.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MAY 16, 1893.

- 497,393.—FAUCET FOR OIL CANS—G. W. Arper, Oakland, Cal.
497,394.—FAUCET FOR OIL CANS—G. W. Arper, Oakland, Cal.
497,743.—FRUIT APPARATUS—M. S. Birdick, Alameda, Cal.
497,463.—OVERFLOW TRAP FOR BASINS, ETC.—E. L. Burgoon, Los Angeles, Cal.
497,806.—BASKET HAMPER—O. H. Carlson, S. F.
497,308.—FAULT DRAIN—C. E. Christman, The Dalles, Oregon.
497,752.—FRUIT-PITTING MACHINE—W. A. Doble, Alameda, Cal.
497,717.—TRAVELING THRASHER—G. Grattan, Stockton, Cal.
497,658.—CULTIVATOR—Harmon & McRae, Milton, Or.
497,768.—RAILWAY SNOW FLANGE—O. H. Johnson, Sisseton, S. D.
497,474.—OIL SEPARATOR—W. P. Miller, Redding, Cal.
497,746.—FARTING CANN—J. R. Phelps, S. F.
497,727.—SHIRT—C. W. Prentiss, S. F.
497,873.—ANALOGATOR—N. L. Rader, Corvallis, Or.
497,314.—WAGON ROAD—T. S. Riddle, Eugene, Or.
497,607.—ANIMAL CUN—B. Riggs Crowley, Or.
497,348.—RAFAIGATOR CAR—P. W. Ross, Los Angeles, Cal.
497,354.—FILTER—T. G. Sortor, Baker City, Or.

The following brief list by telegraph, for May 23 will appear more complete on receipt of mail advices:

- California—John T. Davis, San Francisco, treating of cocoanut husks; Stanley L. Fulford, Los Angeles, gearing for pumps; Charles S. Hamlin, Los Angeles, and metal pipe bell-lock joint; William F. Murray, San Francisco, capstan; Henry E. Poehlman, San Francisco, bumper or stop for cars of underground cable-railway crossings; Samuel D. Roberton, Undine, pipe expander; Albert J. Rogers, Santa Rosa, lubricator; Lee J. Rogers, Pomona, plumb level; Henry C. Royer, Los Angeles, electro-therapeutic apparatus; Carl L. Schallitz, San Francisco, vacuum pan; Charles O. Stallman, San Francisco, combined rotary calendar and stamp-holder; Clarence M. Wolan, San Francisco, breech-loading firearm; James W. Right, Los Angeles, fruit-tree suspender; William S. O'Brien, design for cane.

- Oregon—George F. Moffett, Portland, conduit for electric railway.
Nevada—Jerome Abbel, Reno, stump extractor.
Washington—John M. Bell, Tacoma, district telegraph return-signal key; Thomas A. Terrell, New Whatcom, stump-puller.

Note.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents also general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Mining Share Market.

Until about Wednesday mining shares continued depressed, but on that day there was a reaction and an upward tendency was shown. Orders to buy came from Virginia City, which is always regarded as a favorable symptom. Some good news came from Cons. California and Virginia, Ophir and Potomac which helped the market out. The improvement, however, is not very marked, no great advance of any description having occurred. In another column will be found an article referring to one of the reasons for the depression in Comstock shares.

Market Reports.

The Markets.

SAN FRANCISCO, May 25, 1893.

THE METALS—Tin has developed considerable weakness during the past two days. Copper and lead are unchanged. Silver is in the same situation as for some time past.

Pig Iron.

The report of the New York Metal Exchange for May 18th, says: "The change of feeling within the past two days is very remarkable. Holders have been somewhat conservative in anticipation of a slight advance in freights from the South, but the announced schedule is a complete surprise. It is just possible that some modification may be made in view of the large contracts that are still open, but under any circumstances, those who have iron for sale, require decidedly higher figures than would have been considered a week ago. As a rule, there is a disposition to avoid quoting until the situation is more clearly developed, but some good concerns say they are open to business at fifty cents advance, others quote a still larger advance, but it is just as unlikely that buyers will pay advanced prices immediately, as that holders will continue at the old figures. Those who must buy will have to pay more money, those who can wait will wait, for the present at all events."

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner..... \$550, f. o. b.
 " " " Improved Belt Frue Vanner 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

SAN JACINTO ESTATE, LIMITED,

Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CALICO, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

 MARKET REPORTS—Eastern and Local Metal Markets; Coal and Coke; Sales in San Francisco Stock Board; Notices of Meetings; Assessments, Dividends, etc., 351.

Comment.

In accordance with the orders of the Secretary of the Navy, Rear Admiral John Benham is to command the North Atlantic squadron, and have the San Francisco as her flagship, and the Philadelphia will take her place as flagship on the Pacific Station. We were at first rather inclined to resent the retention of the San Francisco on the Eastern Coast, hoping to have her return to this station where she was built. But she will now stand as a good advertisement of the Pacific Coast shipbuilders and we can afford to spare her, especially if she brings us more orders from the Government. The San Francisco was admitted by all to be the finest looking craft in the recent international naval review and made the best appearance of any craft there. She has also made a fine record as her sea service in the voyage to the East. The Union Iron Works people ought to be proud of the ship and so should the city after which she is named. As flagship of the North Atlantic squadron she will be seen by thousands where she would be seen by hundreds here. Her name will naturally bring forward the fact that she was built here, and her record and appearance will serve a good turn for the Pacific Coast ship-builders.

Mr. John Birkinbine in his presidential address at Montreal before the American Institute of Mining Engineers, discussed the development of technical societies in the United States, and the methods of presenting and publishing technical papers. Mr. Birkinbine says that the discussions which follow the presentation of the majority of these papers are often more valuable than the papers themselves. As a rule they bring out information from personal experience that the original does not contain, and that would only come to light as a discussion by some one who may be a careful observer but lacks the time or inclination to write out what he knows. Some papers do not invite discussion, by reason of their mathematical or other technical form; but these papers should never be read, except in abstract, at a congress or meeting of engineers. They consume valuable time, shut off discussion on more generally interesting papers, cannot be readily digested, and are, in fact, a nuisance to the enforced listeners. The practice now prevailing in a number of technical societies, of printing paper in advance, or at least an abstract of it, is to be commended. It was a happy thought of Mr. Birkinbine to bring this question to the attention of so influential a body as the American Institute of Mining Engineers. Long technical papers, read before a general meeting, and without discussion, are generally wearisome, however valuable the facts presented. There is no opportunity to digest the statements. People would much prefer to have the matter in printed form. It has seemed necessary, however, to read these papers at open meetings, which is one reason that the at-

tendance is generally small at local technical societies. The members know the paper will be ultimately printed and they can read it at their leisure. If, however, they have all read it and a discussion is in order the members will come to the meeting ready to join in it. Printing the papers in advance seems to us the best way, for the meetings of societies are then much more attractive, and when the full proceedings are printed the discussion can accompany the paper.

There is not much chance for the sulphur mines of this State, Nevada and Utah to prove very profitable in view of the imports from Japan and Sicily. The Sicilian producers have been having hard times lately owing to low prices, over production and competition. Three-fourths of the proprietors of the sulphur mines of Sicily lately met and resolved to establish a general syndicate to control the output and sale of the material. The United States is the largest consumer of Sicilian sulphur, taking about 100,000 tons a year. San Francisco uses no more of it, our supply coming from Japan. This amounts to about 8,000 tons a year. The only sulphur deposits now being worked in this country are in Louisiana and Utah. The Cove Creek sulphur beds in Beaver County, Utah, produced about 1200 tons of sulphur in 1891, but new machinery has been put in and its output will be increased. Mining is being carried on by open cuts from 18 to 20 feet deep. The sulphur is extracted from the ore by steam heating in an airtight retort. It is then molded into rolls or blocks convenient for shipping, or ground at the mill for making sheep dip and other preparations. Works of this kind were formerly in operation at the Sulphur Banks in this State, but there is no profit in the business in view of the cheap supplies from Japan.

A few weeks ago the Australasian Institute of Mining Engineers was formerly organized at Adelaide. The avowed objects of the institute are: "To promote the arts and sciences connected with the economical production of the useful minerals and metals, and the welfare of those employed in these industries, by means of meetings for professional papers, and to circulate by means of publications among its members and associates the information thus obtained." This is another advanced step among the professional mining engineers. For a great many years the members of this profession kept their knowledge to themselves as a "stock in trade," and some of them stick to that principle still. However, the majority think differently now and are willing to publish their experience. The American Institute of Mining Engineers is now one of the largest and most influential organizations of the kind in this country, and a great many professional papers are published by the members. When we have added to these the papers which will come from the Australasian Institute, the literature of mining engineering will be greatly enriched.

The Monterey had her sea-trial this week, and, somewhat contrary to expectations, proved a good sea boat. Of course the water washed over her low decks, but that was to be expected. She was more buoyant, however, than was anticipated. The great guns were fired when loaded with projectiles. The accounts of the correspondents who were aboard differ materially as to the results of the firing. One says everything was successful, while another says the Monterey as a fighter was a failure because some defects were found in the gun fittings and turrets. It is probable, however, that any minor defects can easily be remedied now that they are known, and they could not well be known until after practical tests. The official account of the test will not be made public until it has reached Washington. The boilers, about which there has been so much foolish talk, worked in a perfectly satisfactory manner.

Nevada has no State building at the World's Fair, but her exhibit is praised. In the mining department she is said to be making a good show. We do not hear many compliments of our California mineral exhibit; in fact, the remarks about it are the reverse. Here is what the correspondent of the Sacramento *Bee* says about it this week: "Go into the Mining Building, and what do we see? States that make no pretenses whatever of great mineral resources are making a showing that puts California to shame. Yes; California, the Golden West, famed in song and story for her wondrous wealth of mineral stores, has nothing to show. Then go to the California Building and take a look at her mineral display made there—a few la-de-da specimens in pill-boxes. Pass over to any other State building that attempts anything of the kind, and what do you see? A display that makes your head swim—tons and tons of ores exhibited on tables, in sacks, in crates, in truck and carload lots, making you realize immediately that they have the minerals and can show them." Of course this State could have excelled them all had one

been properly prepared. To have arranged something unique and striking would have required brains and to have carried out the arrangement satisfactorily would have required energy. Neither brains nor energy seem to have been put into the California mineral display, though about \$15,000 was set aside for it. This is very unfortunate indeed for the State, which needs outside capital to aid the mining industry. A poor showing, compared with other States, will do us more harm than if we had made no mineral exhibit whatever.

Contesting Legal Hydraulic Mining.

In an editorial paragraph recently, referring to injunctions on hydraulic mines by the Anti-Debris Association, we said: "The miners' time will come, however, and only a little patience is needed. When the Government Commission is organized a license to mine may be procured readily in most of these instances and then operations may be resumed without reference to the Anti-Debris Association or its spies." To this the *Sutter Independent* takes exception and begs to inform the MINING AND SCIENTIFIC PRESS that it is entirely mistaken. It recommends to the PRESS and its clientele a careful reading of those sections of the Caminetti law which govern the matter of petition to the Commission, notice to parties interested, hearing of contents, appeals, etc., and then asks us if we can "do anything without reference to the Anti-Debris Association." Our answer is "certainly, the miners can go on without any reference to the Anti-Debris Association," just as we first maintained. Our statement was that when a license to mine was issued the miners could go on. All the contests, etc., if any are made, must be commenced prior to the issuance of the license, but when once issued, the miners are amenable to the Government Commission alone.

The Debris Commission is compelled to publish the petition of the miner, and all parties interested, either as petitioners or contestants, whether miners or agriculturists, may file affidavits, plans and maps in support of their respective claims. If the Commission decide in favor of the petitioner, they then specify in detail the kind of impounding works necessary (having previously visited the mine). The petitioners must then present plans and specifications, and if these are found to meet the requirements, permission shall be granted to the owners of the mine to commence operations.

The Anti-Debris Association can of course make a contest in every case where a petition is filed, and doubtless will, if it pursues its usual policy. And it will have its hands fuller than it ever did before when it undertakes this job, too. Mr. W. T. Phipps, the manager of the association, tells the taxpayers of the counties from whom he derives his salary that "this Debris Commission will, in the future, be to us what the courts have been in the past, and if we wish full protection before that body we must be in a position at all times to present necessary facts, upon which that body shall act—at least for some years yet to come, until the commissioners shall become fully conversant with all the details of our claim. Hence you see the necessity of maintaining an organization who shall make this work of getting proofs its business."

It is evident from these remarks of the *Independent* and of Mr. Phipps that the Anti-Debris Association intends to continue its policy of obstruction whether the miners try to obey the laws or not. Now, no one can find fault with them for obstructing, arresting and punishing those who mine illegally, but when the miners endeavor to comply with the law a policy of constant obstruction can only end in defeat. A law has been made by Congress by which the hydraulic miners can pursue their avocations under certain specified restrictions, and the more recent decisions of the courts are on the same line. Those miners who honestly endeavor to comply with the provisions will be protected by the courts and the Commission.

It is our opinion, too, that Mr. Phipps will find himself mistaken with regard to the Commission being to the Anti-Debris Association what the courts have been. This Commission will treat the matter from an engineering standpoint altogether and not make decisions on legal technicalities or local prejudice. The law compels them to examine each individual mine from which a petition is received, and they will therefore have a more intelligent knowledge than court officials who never saw the properties in dispute.

Moreover, this subject of hydraulic mining, debris, and river protection has passed from the domain of law into that of engineering. The legal features have been decided; the engineering problems are still to be solved. The Commission which has the matter in hand is to do its work under a special Act of Congress, and its duties as specified are such as require engineering, not legal, knowledge. If they find that a mine can be operated without injuring the navigable streams, after examination and consideration of all the circumstances, they will issue a license. They are

not a class of men to let prejudice, malice, or technicalities, influence them in any way. If they think the mine is in a situation where it cannot be operated without doing harm, they will issue no license.

In the decision of the matter from an engineering standpoint, the miners will have an advantage which they have not had before the courts in the past. Every claim must be visited by the engineers or their assistants, and every claim will have its particular situations and surroundings examined. There will be no general decision as to right to mine or stoppage of mining. The MINING AND SCIENTIFIC PRESS has never upheld those men who have injured the hydraulic mining industry by violating injunctions or breaking the laws, but it does believe that hundreds of hydraulic mines could have been at work all these years if it were possible for fanaticism to listen to reason. It believes, too, that under the provisions of the Oaminetti Act the hydraulic mining industry in California will be rehabilitated in due time, notwithstanding the obstructive efforts of individuals as opposing associations.

Working South Africa Gold Mines.

The Witwatersrand district, Johannesburg, South Africa, continues to turn out great quantities of gold. The latest complete returns are those for March. Forty-seven companies milled in that month 117,291 tons of ore with 1789 stamps during twenty-seven days milling. This was equal to 3.65 tons per stamp per day. The total yield of gold from the milling was 84,235 ounces valued at £304,516. Concentrates yielded 5460 ounces valued at £21,809. In two cases the concentrates were worked by MacArthur-Forrest process and the other three cases chlorination process was used. In working tailings one mine used the Molloy process, one chlorination, one "cyanide" and eighteen used the MacArthur-Forrest process. The total tailings worked in the month yielded 13,877 ounces valued at £62,021. From alluvial workings 200 ounces were obtained valued at £680 and from other sources 2699 ounces were obtained valued at \$9447. The total yield of the camp for the month of March was 111,474 ounces of gold valued at £398,473. The value of gold is generally about £3 10s per ounce. The biggest mines are all using the MacArthur-Forrest process. The new Primrose, for instance, which milled 10,800 tons of ore, worked 17,500 tons of tailings by this process. The total yield for the month was 7336 ounces worth £24,940. The Robinson which worked 8201 tons in the mill and took out £32,632 got £11,084 from its tailings. The Langlaagte estate which worked 19,120 tons at its mill also worked 11,024 tons by the MacArthur-Forrest process. The Durban Roodepoort mine, which milled 6750 tons, worked 8100 tons of tailings. The Crown Reef, which milled 9744 tons, worked 8308 tons of tailings. With three exceptions all the mines on the list which were working over their tailings are using the MacArthur-Forrest process to recover the gold.

The camp of Witwatersrand is now turning out more gold annually than the whole State of California and is, for the present, the leading gold producing section of the world. The material from which the gold is obtained is a conglomerate, like a cemented gravel, and is not quartz like we have in our ledges here. It is very hard and has to be crushed in mills just like quartz. The gold is not of a very high grade, in fact some of it is very poor as compared with what we find here.

A Silver Mill for a Mexican Mine.

The engravings on our first page show a plan and elevation of a new pan-amalgamating silver mill, constructed by the Risdon Iron Works for the Tabor mines and Mills Company, Santa Eduwiges mines, in the Jesus Maria District, Chihuahua, Mexico. It corresponds in nearly all respects to a very successful mill recently built by the same company for the Candelaria mines, San Dimas, Durango, Mexico. The new mill has a capacity of treating from 60 to 100 tons of ore daily, and except the Candelaria mines, which has the same capacity, is the largest installation of the Bryan roller mills for crushing that the company have erected.

The motive power consists of a compound Corliss engine with cylinders 12 and 20 inches diameter, 22 inches stroke, sufficient for four 4-foot Bryan mills, eight 5-foot pans, and four 8-foot settlers, with other details of the mill requiring power. The boilers, two in number, are tubular, 54 inches diameter, 16 feet long.

The Bryan roller quartz mills, which have been described in the MINING AND SCIENTIFIC PRESS, are a main feature of the plants named. More than fifty plants have been supplied with these mills, with uniform success. The following, from the company's circular, will furnish the main points in respect to the advantages of this method of crushing:

"The old arrastre which probably was used dearlier than

stamps, is still in use in its crude form, and in many instances considered superior to new and improved machinery. The arrastre 'did the work' and did it well—and so did the Obilian mill, which may be considered developed from the arrastre. But greater capacity was required, and as the stamp battery at that time was the only machine arranged for continuous crushing, it took the lead, as its capacity was so much greater. As for amalgamation, the principle of the arrastre and Chilian mills was considered superior to stamps. Many different kinds of roller mills were tried, but they were too complicated and difficult to keep in repair, and the oil could not be prevented from dropping into the pulp, which made the quicksilver unable to amalgamate with the gold. It was after many years of experimenting, and at considerable expense, that the Risdon Iron Works were able to so improve these machines that they now have all the advantages of the crude arrastre and Chile mill, and at the same time possess the simplicity and durability that is required in mining machinery."

These mills are driven by a direct band without gearing. The drawings of the complete plant are clear and require no detailed description. At the Candelaria mill, one man, a common laborer, attends the whole crushing plant, which reduces from 60 to 100 tons of ore daily.

A Company For Selling Mines.

In another column will be found a copy of the articles of incorporation of a company which proposes to handle mining properties on a plan which looks as if it were a good one for the mine-owners and purchasers. The incorporators are all men of standing in the community and of practical experience in mining affairs. They intend to act as agent for eastern and foreign mine-owners and will have correspondents in New York, Chicago, London, Paris, Berlin and other cities. The main feature of the organization is that which provides for assisting miners and prospectors to dispose of properties without their being over-loaded by middle-men, and mines will be advertised for sale just as real estate is offered. The policy is this, when a man comes in and reports a mine to be worth \$40,000 and wishes to list the same with the company, it will send one of its experts out to verify his statement. If verified the company will offer his mine for sale at his own figure and charge him a commission for selling. This enables the buyer to get a mine at bed-rock figures, and the seller at the same time gets his price less the commission of course, which will be agreed upon.

Several attempts have been made at various times to establish mining bureaus, mining agencies, etc., for the sale of mines, but none have been successful either because the originators were irresponsible and took any property that came along, or because they were mere middle-men working under a company's name. They have not guaranteed the statements made by the would-be sellers or taken steps to verify reports. As we understand it, this new organization will first satisfy itself, through its experts, of the value of the property and then offer it for sale. It is only intended to handle legitimate mining properties which have some prospective merit.

Another feature will be furnishing information to non-residents concerning properties in which they are interested. That is, they will obtain information in regard to mines and impart this on receipt of a fee. It will have nothing to do with mining stocks one way or another, legitimate mining being its only sphere. From its articles of incorporation the company itself is prohibited from purchasing as a corporation any mining property which is offered to it for sale. This is a provision which no similar organization has had, and it is an important one, confining the company to its legitimate functions as an agent. The incorporators of the new company are: Irwin C. Stump, Irving M. Scott, J. H. Neff, W. F. Goad, R. C. Chambers, P. N. Lilienthal and D. M. Burns. The secretary of the company is to be Wm. C. Ralston. Offices are to be taken in the Mills Building and the company will shortly be ready for business.

BRITISH COLUMBIA HYDRAULIC MINES.—W. C. Ralston, the mining engineer, received a letter recently from J. B. Hobson, who is mining for some of the Canadian Pacific Railway people in British Columbia, stating that he would leave on the 20th of May for the Horse Fly Country in British Columbia to commence the work of equipping the Discovery mine for hydraulic mining. They will use 2000 miners' inches of water brought to the mine through ditches and flumes only ten miles in length. At the mine they will use 11,000 feet of 30-inch steel pipe, 3000 feet of 22-inch and 2000 feet of 18-inch and 3 No. 7 giants. The gravel bank averages 100 feet high and is claimed to be worth 20 cents per cubic yard.

What a wonderful change it would make in California if it were possible to operate hydraulic mines again without restriction and without injuring the navigable rivers.

Coast Industrial Notes.

FROM Santa Cruz to Santa Barbara this coast abounds in crawfish and arrangements are being made to catch them in quantities. Some will be sent East alive in cars, some will be sent cooked and some spiced in vinegar. A factory will be established in Santa Barbara county.

The new machinery at the Bay City mine, El Dorado county, between Enterprise and Plymouth, has been erected, and was to be started this week. It was put up for the purpose of sinking the shaft to the depth of about 1000 feet, for which the machinery previously in use was inadequate.

THE new steamer Weecott, which has just been built at the Oakland shipyard, has been brought to Vallejo-street wharf to be fitted up. The Weecott will have an electric plant and other modern appliances. The vessel is 130 feet long and has a beam of 29 feet. It will be in charge of Captain Yarnberg, and will run between this city and Eel river. The Weecott is the property of Russ, Sanders & Co.

TRACK-LAYING for the new Mission-street electric road has been completed to Seventh street, and in about four weeks the road-builders will reach the ferries and finish track-laying. The Twenty-ninth-street branch, from Mission to Noe street, is nearly finished, the ties and rails already being in, and the macadamizing the roadway almost completed on the portions required to be paved by the railroad company.

AT the present time 2178 men are directly engaged in the labor of catching and canning salmon at Astoria, Oregon. Of these 175 are working on the fish traps, 1300 are gill-net fishermen, working in fishboats, and the balance—703—are employed in canneries cutting, filling, slicing and cleaning the fish, and canning, soldering and packing the tins. Among the latter are 640 Chinamen, who constitute the entire number of Mongolians employed in the business. There are 650 boats employed.

THE West Coast Furniture Company of this city which employs from 300 to 400 men have decided to make a ten per cent. reduction in the wages of the mill hands. The decision affects about 75 men who refuse to consider the proposition. The owners of the mill, L. & E. Emanuel, say that unless the hands accept the situation they will have to shut down until business revives, as the furniture manufacturing industry is exceedingly dull at present. The men threaten to place the matter before the Federated Trades.

THE fishing schooner St. Lawrence, Captain T. A. Green, arrived at Ainsworth & Dunn's dock, Seattle, the other day with about 40,000 pounds of halibut. This is the third successful fishing trip of this schooner since she was built, and the present catch is the most valuable of the three. Captain Green says he did not intend to go farther than Flattery banks, as heretofore they have been able to get halibut there by the first of May; but after waiting five or six days there and catching on six or seven fish, he went again to the Northern banks and the fish brought in was all caught in two days.

ARTICLES of incorporation of the Southern California Manufacturing Company with the principal place of business at Pomona, have been filed in San Bernardino county. The capital stock is placed at \$50,000. The directors are: John H. Dale, C. E. White, H. P. Wilkinson, John E. Packard and James H. Todd. The company will derive its power from the San Antonio Electric Light Company and from the new plant now being erected on Mill creek, near Redlands. It is estimated that these sources will supply several thousand horse-power for manufacturing purposes in the day time and for lighting Redlands and San Bernardino and other cities at night.

SAN DIEGO fishing interests are on the increase. In 1889, San Diego shipped by the Pacific Coast Steamship Company alone 388,370 pounds of fish; in 1890, 463,360; in 1891, 467,260, and in 1892, 566,360 pounds. Up to 1891 there had never been a pound of fish pickled in brine shipped out of San Diego. In October, November and December they pickled and shipped 5260 pounds as a flyer or experiment. It proved so successful that in 1892 they pickled and shipped 124,900 pounds. How is that for an increase in twelve months? At present barracuda are running in large numbers and the catch is very heavy. Mackerel are also coming in and the catch promises to be unusually large. The albacore we have always with us on the banks about ten or fifteen miles out.

J. J. MOSTON and Mr. T. HAMMER have a force of men at work constructing a mining ditch from a point one and a half miles from the mouth of Grouse creek to the mouth of the South Fork of the Trinity river, 35 miles from Blue Lake, Humboldt county. Some time ago Mr. Moston sold a half-interest in this mining property to Mr. J. L. Kellison, and while they are likely to dispose of it at any time to a syndicate of capitalists, it is, nevertheless, among the probabilities that they will retain it until the ditch they have undertaken shall be completed and they are ready to work the extensive beds of gravel its construction will make easy. The Blue Lake Advocate is assured that an abundance of water, which this ditch will provide, will render possible the working of 1280 acres of gravel. The first of these beds lies at a point four miles from where the ditch begins, and they are scattered along the entire eighteen miles of country that it will traverse. There are a number of good mines in that section, Mr. Moston says. Among them may be mentioned Mr. A. N. Foote's claim, situated on Trinity above the mouth of Willow creek; the Russell mine, below the mouth of Willow creek on Trinity; the Arcata claim, owned by Mr. T. E. Knight and other Arcata parties; the "Poor Man's Friend," a Trinity mine one and one-half miles above the mouth of Willow creek; and the Dungan mine, situated perhaps one and a half miles above the Foote claim. Of these the "Poor Man's Friend" is a valuable property, and so is the Dungan mine which, as Mr. Moston expresses it, wants only water upon it so that the gold that is assuredly there in large quantities may be taken out.

The Mines of Southern Oregon.

[From our Special Correspondent.]

TO THE EDITOR:—The mines of southern Oregon, which in the past have been but little known and talked of outside of their own locality, are now attracting considerable attention among prospectors and capitalists all over the Pacific coast. This is all owing to a few energetic men, both capitalists and prospectors, who were not afraid to back their judgment with unremitting labor and capital. It has been the popular belief among mining men for years that southern Oregon contained no standard mines of any importance, but the development of the Ashland mine and others proves the incorrectness of this belief. Although they have some good mines in southern Oregon and more are being developed, still it does not compare favorably with the quartz mining districts of California, in regards to richness and extent of ledges.

The geological formation of the mineral belt in Josephine and Jackson counties, taken as a whole, is of a pockety nature and the mineral bearing ledges small and irregular in width, as a general rule. Porphyry, strongly impregnated with iron and lime, is predominant throughout the formation of the mineral belt, although in some localities every class of formation existing in the mineral belts of the coast may be found all mixed up together showing evidence of simultaneous upheavals of the earth's crust at some remote period in those localities. Those spots, so to speak, occur principally in the northern portion of Jackson county and the southwestern part of Josephine, and are productive in small pockets which seldom exceed a few hundred dollars, with the exception of some late discoveries. There have only been two large pockets discovered so far in southern Oregon, viz: Gold Hill and Steamboat, and it is the current belief among prospectors and miners that where there are one or two large pockets such as there were found, there must certainly be more, yet undiscovered.

Gold Hill produced over \$129,000 while Steamboat yielded in the neighborhood of \$246,000, as near as can be learned from the most reliable authority, and although some 20 miles apart, yet they were both discovered in this mixed formation. Within the last few months several good pockets have been discovered in Jackson county in what is known as the Blackwell hills between Gold Hill and Jacksonville, but the largest, amounting to something over \$4000, was discovered by Mr. D. Horn, on Galls creek, about four miles from Rock Point.

Among the energetic capitalists who are expending money to prove whether the ledges go down to any great depth or not and still carry gold in paying quantities, are the Schieffelin Bros., well known in mining circles in connection with the Tombstone mines of Arizona. They are operating on Foot's creek some ten miles from Gold Hill.

Ashland is at present the center of attraction for mining men and prospectors. Some very good prospects are being developed at present in that vicinity which promise to become good-paying properties and quite an active boom in mining is the result. The formation in this district is favorable for permanent gold-bearing ledges, and no doubt this district will attract considerable attention from capitalists in the future. The placer mines of southern Oregon were rich when worked in the early days, and wherever rich placer mines existed over a large scope of territory, good quartz mines have been developed afterward, as a general rule. The prospector who is unacquainted with this country will find a difficulty in prospecting here that he does not meet with further south.

On the north side of the Siskiyou range the country seems older and more broken and the formation covered with a greater depth of soil than it is on the south side of the mountains, which makes it difficult to prospect in, but the greatest obstacle that the prospector will find in his way is slides. In this broken up formation innumerable slides have occurred at some remote period and moved parts of the formation and ledges with them intact, covering the formation underneath sometimes to the depth of 50 feet or more which makes prospecting in such localities slow and expensive. But in the course of a few years capital combined with improved methods will overcome this difficulty and uncover the blind ledges and make to them yield up their store of mineral treasure. ALEX. QUARTZ.

Ashland, O., May 27, 1893.

Money Spent in Fighting the Miners.

TO THE EDITOR:—As the question of debris is once more before the public, it would be interesting to your readers to know how much money has been contributed by the various counties towards paying attorneys, officers and spies of the Anti-Debris Association.

From reliable sources it is learned that the Board of Supervisors of Sacramento county paid to that association \$80,000, Sutter county paid \$75,000, Yuba county \$65,000, San Joaquin county \$11,000, Colusa county \$10,000, Yolo county \$10,000 and Butte county \$4,000, making a total of \$254,000 from seven counties. To this must be added nearly \$100,000 which was contributed by individuals, and also \$40,000 which was appropriated by Congress to prosecute the miners, making a total of \$394,000. The question naturally follows: What has been done with this money? If an accounting were in order, to whom do they account?

A SUBSCRIBER.

The Mexican Export Tax on Metals.

The Treasury Department has issued a ruling to the effect that gold and silver ores, in their natural state, that is, ores which have not been subjected to any chemical process altering their natural composition, shall not be subject to the assay dues on their exportation.

This reverses the ruling of Feb. 25th, 1892, which has been felt as a severe hardship by the mining interest, and which imposed a tax on ores exported in a pulverized state, whether occurring so naturally or reduced to that state by treatment in the mill.

The new ruling declares explicitly that ore will be held to

be in its natural condition, and therefore will not be taxed on its exportation, even after it has been triturated or subjected to other mechanical process, provided it has not been treated chemically. If it has been so treated it will be subject to the export tax.

The decree, furthermore, provides that if silver in slag, precipitates, amalgams, sulphides, chlorides, or other artificial form, be found mixed with the ore in its natural state, the export tax shall be levied with respect to the whole shipment, including the natural ore, and the fines created by the Tariff for cases of fraud shall be enforced.—The Mexican Financier.

The Pacific Mining Agency and Trust Company.

The articles of incorporation of the Pacific Mining Agency and Trust Company, dated May 25, 1893, are as follows:

Know all men by these presents:—That we, the undersigned, a majority of whom are citizens and residents of the State of California, have this day voluntarily associated ourselves together, for the purpose of forming a corporation under the laws of the State of California.

First:—That the name of said corporation is the "Pacific Mining Agency and Trust Company."

Second:—That the purposes for which it is formed are: To buy and sell mines, mining claims, water and ditch properties and water-rights on commission; to act as agent and broker for the sale and purchase of mines, mining claims, water and ditch properties and water-rights; to act as agent, broker or factor for the owner or owners of mines, mining properties, water and ditch properties and water rights, to obtain, acquire and secure information of every kind relating to the merits, value and titles to mines, mining claims, water and ditch properties and water rights; and to trade and deal in and with such information, and generally to do or perform any other act or thing necessary or proper for the carrying out the purposes herein mentioned; but said corporation shall not engage in the business of buying or selling mines, mining properties, water or ditch properties or water rights except on commission, or as the agent or broker or factor of others.

Third:—That the place where its principal business is to be transacted shall be the City and County of San Francisco, State of California.

Fourth:—That the term for which it is to exist is fifty years from and after the date of its incorporation.

Fifth:—That the number of directors or trustees of said corporation shall be seven and the names and residences of those who are appointed for the first year are: Irwin C. Stump, San Francisco; Irving M. Scott, San Francisco; Jacob H. Neff, Placer County; W. F. Goad, San Francisco; R. C. Chambers, Salt Lake City; P. N. Lillenthal, San Francisco; D. M. Burns, San Francisco.

Sixth:—That the amount of capital stock of said corporation is \$250,000, and the number of shares into which it is divided is 2500 of the par value of \$100 each.

Seventh:—That the amount of said capital stock which has been actually subscribed is \$3500 and the following are the names of the persons by whom the same has been subscribed, to wit: Irwin C. Stump, 5 shares, \$500; Irving M. Scott, 5 shares, \$500; Jacob H. Neff, 5 shares, \$500; W. F. Goad, 5 shares, \$500; R. C. Chambers, 5 shares, \$500; P. N. Lillenthal, 5 shares, \$500; D. M. Burns, 5 shares, \$500.

Should Give Assistance.

The silver mine owners of Colorado, Nevada, Idaho and Montana are trying to play the part of cunning sharps; they know the question of free coinage is of greater importance to the masses than to themselves and as a result refuse to donate anything substantial toward carrying on the fight. Right here in Colorado we know of thirty mine owners who absolutely refuse to extend a single cent to the silver committee, preferring to let their ore stay underground until poverty squeezes the farmers and mechanics into making the fight so hot that free coinage is granted.

It is unfair, and if it wasn't for injuring merchants, farmers, manufacturers and mechanics we would drop the silver fight right here and let the stingy mine owners fight for themselves. There are 1000 mine owners in the silver States who could well afford to put up \$10,000 apiece to aid the silver fight (with an absolute guarantee that their money would come back to them in two or three years) and not feel the loss a bit, but they gig back their big arm-chairs and selfishly remark: "Oh, it is no skin off our nose! Our ore is in the ground and it will not run away. We can afford to wait. You fellows must have free silver or go to the wall."

Ah! that may be so, but there is just the possible chance the people will consent to a paper inflation equal to the amount that would arise through remonetization of silver. Then, Mr. Mine Owner, where would you be?

In the battle to right the crime of 1873 mine owners should do their part. They are not doing it now, not by a long way.—The Road.

An Important Mining Decision.

Not a great many suits for trespass with damages asked in the sum of \$2,000,000 have been tried in this country. The jury in a trial before Judge Knowles in the United States Circuit Court at Helena last week found for the defendant in the suit of the St. Louis Mining Company, against the Montana Company, limited, for the wrongful extraction of ores. The defendant company is commonly known as the "Drum Lummon," and has paid its stockholders, mostly Englishmen, several millions in dividends. The plaintiff company is owned by Montana and St. Louis people. Their properties adjoin and are located at Marysville, a few miles north of Helena.

Preparations for the trial have been going on for six years, the contention being that the apex of the Drum Lummon vein was within the side lines of the St. Louis

claim, which under the United States statutes, the St. Louis Company was entitled to follow. The defense was that the alleged vein in the St. Louis claim was not a vein.

Ten mining experts and geologists have been in attendance since April 24th. Their charges have aggregated about \$3000 per day for the time spent in examining the mines. Three stenographers have averaged \$50 daily each during the trial. Add to these the necessary court expenses for a trial lasting thirty days and a total of \$100,000 is reached, exclusive of attorney's fees. The experts for the plaintiff were C. S. Batterman of Aspen, Col.; Carl Hand of Butte; A. D. Churchill, John R. Parks and G. G. Swallow of Helena. For the defendants there appeared Rossiter E. Raymond of New York; Charles Goodale, superintendent of the Great Gagnon mine at Butte; C. A. Molson, superintendent of the Elkhorn mine; George H. Robinson of Utah, formerly manager of the Drum Lummon, and Henry Bratnoble, who helped to sell the Drum Lummon to the English company. The attorneys for the St. Louis company were Warren Toofe, N. W. McConnell and John B. Cleyberg of Helena, while W. E. Cullon of Helena, Charles Hughes Jr. of Denver and Judge M. Kirkpatrick of Butte represented the Drum Lummon Company.

The case has been not only notable in that it involved such a large sum, but also because of the great expense attending it. The experts on both sides were high-priced men, and in this one item alone the fees amounted to over \$100,000, and altogether the costs, exclusive of the lawyers' charges, will reach \$150,000.

Prizes for Scientific Research.

In October, 1891, Thomas George Hodgkins, Esq., of Setauket, New York, made a donation to the Smithsonian Institution, the income from a part of which was to be devoted "to the increase and diffusion of more exact knowledge in regard to the nature and properties of atmospheric air in connection with the welfare of man." With the intent of furthering the donor's wishes, the Smithsonian Institution now announces the following prizes to be awarded on or after July 1, 1894, should satisfactory papers be offered in competition: 1. A prize of \$10,000 for a treatise embodying some new and important discovery in regard to the nature or properties of atmospheric air. These properties may be considered in their bearing upon any or all of the sciences—e. g., not only in regard to meteorology, but in connection with hygiene, or with any department whatever of biological or physical knowledge. 2. A prize of \$2,000 for the most satisfactory essay upon (a) The known properties of atmospheric air considered in their relationships in research in every department of natural science, and the importance of a study of the atmosphere considered in view of these relationships. (b) The proper direction of future research in connection with the imperfections of our knowledge of atmospheric air, and of the connections of that knowledge with other sciences. The essay, as a whole, should tend to indicate the path best calculated to lead to worthy results in connection with the future administration of the Hodgkins foundation. 3. A prize of \$1,000 for the best popular treatise upon atmospheric air, its properties and relationships (including those to hygiene, physical and mental). This essay need not exceed 20,000 words in length; it should be written in simple language and be suitable for publication for popular instruction. 4. A medal will be established under the name of the Hodgkins Medal of the Smithsonian Institution, which will be awarded annually or biennially, for important contributions to our knowledge of the nature and properties of atmospheric air, or for practical applications of our existing knowledge of them to the welfare of mankind. This medal will be of gold, and will be accompanied by a duplicate impression in silver or bronze. The treatises may be written in English, French, German, or Italian, and should be sent to the Secretary of the Smithsonian Institution, Washington, before July 1, 1894, except those in competition for the first prize, the sending of which may be delayed until Dec. 31, 1894. A principal motive for offering these prizes is to call attention to the Hodgkins Fund and for the purposes for which it exists. Suggestions and recommendations in regard to the most effected application of this fund are invited. It is probable that special grants of money may be made to specialists engaged in original investigation upon atmospheric air and its properties. Applications for grants of this nature should have the indorsement of some recognized academy of sciences, or other institution of learning, and should be accompanied by the evidences of the capacity of the applicant, in the form of at least one memoir already published by him, based upon original investigation. To prevent misapprehension of the founder's wishes, it is repeated that the discoveries or applications proper to be brought to the consideration of the committee of award, may be in the field of any science or any art without restriction; provided only that they have to do with "the nature and properties of atmospheric air in connection with the welfare of man." Information of any kind desired by persons intending to become competitors will be furnished on application. All communications in regard to the Hodgkins Fund, the Hodgkins Prizes, the Hodgkins Medals, and the Hodgkins Fund publications, or applications for grants of money, should be addressed to S. P. Langley, secretary of the Smithsonian Institution, Washington, U. S. A.

THE CARSON MINT.—A saving of \$65,000 per year will be made by Secretary Carlisle by the suspension of coinage at the Carson Mint, in Nevada, after the close of May. The mint at Carson is the least important in the country. Only about \$100,000 a month was deposited for coinage in gold bullion, and the expense rose to nearly 8 cents per piece at Carson, against 1½ cents at Philadelphia and less than 1.2 cents at New Orleans. The suspension of coinage will dispense with the services of some forty employees, receiving wages of \$50,000 per year, and will save incidental expenses of from \$12,000 to \$15,000. The mint will not be altogether closed, but will be kept open for receiving gold and silver bullion, for parting and refining, and for the purchase of silver bullion under the Sherman act.

The Storage of Water for Irrigation.

The *N. Y. Independent* is doing an excellent work in educating the Eastern mind on the subject of irrigation for the arid lands. It has recently published articles from many special students of irrigation, one of which we reproduced in last week's *PRESS*. We now make other selections from the same source; first, from A. P. Davis' article on "Storage of Water for Irrigation," as follows:

The problem of water storage for irrigation is a very different one from that for the domestic supply of a city. In the first place, it is important that water for domestic use be as nearly as possible free from mud and organic impurities, while for irrigation such impurities are not only no objection to the water, but often materially add to its value by enriching the soil to which it is applied. In the second place, it is far more easily defeated by the expense of construction. A city of a hundred thousand people may consume no more water for domestic use than would be required to irrigate a square mile of land in the arid region; but such a city may very easily and conveniently pay for its supply several hundred thousand dollars, a sum many times as great as could be afforded for the same water for irrigation.

The range of capacity in proportion to cost, and the distance the stored waters can be carried, is, therefore, far less in the case of reservoirs for irrigation than for domestic supply, and only such sites as have large capacity and exceptionally favorable dam sites can be used.

In the selection of reservoir sites regard must be had to several considerations. The area and character of land to be irrigated, and its distance from the proposed reservoir. The area of the watershed, the drainage from which is to fill it, and both the maximum and minimum annual rainfall of the watershed. If the quantity and value of the land to be watered and the capacity of the reservoir are great, as compared with the available water to be stored, it may be advisable to build a reservoir of sufficient capacity to contain much more than the minimum annual run-off, so that the discharge of wet years may be saved for use in time of drought.

The mean discharge of streams varies considerably with the topography of the basin, and with the character of the soil and climate. A basin composed largely of very steep, rocky, barren mountain sides, will discharge a larger percentage of its rainfall than one that is comparatively flat and covered with soil and verdure, and its floods will be far higher and more sudden. In an arid region it is never safe to count on storing more than 50 per cent. of the rainfall, and in many cases the available supply will fall below 40 per cent.

RESERVOIR SITES

May be divided into two great classes: Natural lakes or depressions, and reservoir sites on drainage lines.

Lakes often afford large storage capacity with small expense for outlet cut or tunnel, and perhaps a small dam or dams. Such dams as may be necessary to afford the required capacity can more often be constructed of earth than in the case of reservoirs on streams, as the foundation is far more likely to be of fine sand or loam rather than rock or shale. Such sites have two important advantages—the dams are not endangered by the enormous floods that are bound to occur on streams, and an opportunity is afforded for disposing of the rock and silt from the storm waters stored, before they reach the reservoirs.

The chief expense attending this method of storage is usually the diversion and transportation of water from some neighboring stream, and this expense is very greatly increased from the fact that the volume of water to be conducted is never constant, but comes chiefly in floods discharging several hundred times the average flow of the stream, and in order to approximate its conservation a canal must be built large enough to carry the heavy floods, unless storage can be provided on the stream itself. Where a large natural basin occurs in reach of an important stream affording a small subsidiary reservoir site at a higher elevation, the conditions for water storage are ideal.

The selection of a suitable reservoir site on a stream is no simple task. The fall of the stream, and the slope of the adjoining land toward the stream, is often very deceiving to the unpracticed eye, and the area of the reservoir consequently much smaller than it looks.

The average depth of such a reservoir is seldom over two-fifths the height of the dam, and often less than one-third, making the capacity far less than may appear.

A careful set of borings is usually necessary to determine the depth of excavation to a suitable foundation for a dam and the character of such foundation. An ample spillway must also be provided; this, as has been well said, is the most important part of the work, as more dams have failed from defective spillways than from bad construction.

CONSTRUCTION OF DAMS.

Dams may be built of earth, loose rock or masonry, or of a combination of these materials. Earthen dams, where practicable at all and not too high, are usually far cheaper than those built of rock; and this, as we have seen, is nearly always the determining feature of water storage.

An earthen dam must have a broad foundation of some kind of earth, preferably a clayey or sandy loam, but never of rock or shale. Suitable material for construction must also be at hand. This should consist of any kind of fine, homogeneous earth, nearly free from coarse gravel, rock and shale. The dam must, of course, be water-tight, not only to prevent the escape of water, but to prevent its own destruction. This is sometimes accomplished by means of a masonry core, consisting of a thin masonry dam built up the center of the embankment; sometimes by a core of puddle work, of selected material solidly rammed to prevent leakage, and sometimes the face of the dam is composed of such puddle work. The most approved modern method, however, is to make the entire embankment as nearly impervious as possible by carefully excluding rocks and other coarse materials, and having the embankment well rolled and tramped throughout its construction. A

submerged puddle core should, however, be built the entire length of the dam to prevent seepage under it, and should extend for several feet above the base of the embankment. The slopes given should be considerably flatter than the angle of repose of the material used in construction, especially on the interior face, which will be exposed to the action of the water. This should also be faced with rock rammed into place in order to neutralize the erosive action of waves.

Loose rock dams are constructed of rock laid with some care, without mortar, and should be built as solidly as possible, to reduce settlement to a minimum. To render it impervious to water, an apron is built on the upper slope. This apron may be of tarred planking, or an earth embankment, or it may consist of a sort of rubble masonry laid in rich asphalt, which has sufficient elasticity to conform to the settlement of the structure if well built. The apron must be carried down to impervious bedrock to prevent percolation under the dam. The cross-section must, of course, be sufficient to enable the dam to resist the water pressure by gravity alone. Except where rock is scarce, or transportation very cheap, or suitable earth distant, a masonry dam is more expensive than the ones above described. There are some situations, however, where it is the only practicable form, and others where it is cheapest, and it is always more ornamental. It is usually built in the form of an arch, with the convex side up stream. It is desirable to use as large rock as possible, as this economizes cement and makes the structure stronger. The mortar must be carefully mixed and well rammed into all joints and crevices. The mortar used on the up-stream face must be very rich, so as to prevent leakage.

Every dam must have a spillway. A masonry dam may itself be a wastewear, provision being made to prevent the washing out of the foundation by the shock of the water. It is better, however, to have a spillway at some distance from the dam, over a saddle in the hills, or, if necessary, through an ample tunnel. This is especially the case with earthen or loose-rock dams, as it is difficult to build a safe wastewear over them.

It is, of course, necessary to provide outlet sluices from a storage reservoir, and these may be either through a dam, or, preferably, through the hills in some other part of the reservoir. These sluices, the gates for controlling their discharge, and the machinery for working the same, must always be accessible for examination and repair.

PREVENTING SILT DEPOSIT.

In most parts of the arid region the storm waters, which are the main source of storage water, carry large quantities of rocks, sand and silt, and introduce, perhaps, the most serious problem with which the irrigation engineer must contend, viz., how to prevent the filling of the reservoir with detritus. Some attempts have been made to deal with this difficulty by constructing dams with several sluiceways through the bottom, through which the water is allowed to rush at times to wash out the silt. This method is by no means satisfactory, as the sluices weaken the dam, the floods allowed to pour through waste large quantities of water, and only that silt near the sluiceways is removed.

A very effective method, where possible, is to locate the reservoir at some point not on the stream from which it is to be filled, and to lead the water by a canal from the stream to the reservoir. At some convenient point on the canal a flume is inserted over a cross-drainage line, so that the flume will be six or eight feet above the ground, and a sand-box or section of the flume constructed wider and deeper than the rest, with its bottom several feet lower than the grade of the canal, so that it will be constantly filled with water flowing at a very low velocity, and in this the water will deposit its load of sand. Large gates are placed in the bottom of the box, which can be quickly opened to allow the sand to drop out, and waste little or no water. The floods in the cross-drainage line are supposed to carry the sand away, or it can be removed with scrapers. The larger the sand-box the more completely will the silt be deposited, and the less frequently will it require opening.

Where the reservoir is situated on the stream that is to fill it, the following method may sometimes be employed for removing the debris: A small reservoir may be constructed up stream, as much higher than the main reservoir as practicable, and the water piped down under pressure, and at favorable periods the sand and gravel may be washed out by hydraulic force, as in placer mining, and allowed to run through sluices provided through the bottom of the dam.

If the flow of the stream is suitable, it may not be necessary to construct an upper reservoir, but only to divert the stream into pipes high enough up to secure sufficient hydraulic force.

This method is effectual but expensive, and not always practicable, as the fall of the stream may be too low to give sufficient hydraulic force without going so far away as to render the cost prohibitory.

The disposal of silt deposited in reservoirs still remains one of the serious problems of irrigation engineering; but, as water and irrigated land become more valuable, as they inevitably must, and storage systems multiply as they are now doing, the combined experience and ingenuity of our engineers will undoubtedly suggest plans and improvements that will constitute its practical solution.

The Eucalyptus.

The eucalyptus tree is a native of Australia and Tasmania, where it forms large forests. There are about 140 species described, but they vary extremely, different kinds of leaves being produced on the same tree, thus presenting distinct specific characters and varying also in the nature of their barks.

In Tasmania and Gippsland, Victoria, they grow to an immense height, often exceeding 400 feet. Their naked and branchless stems of a dirty white color look like natural columns. These are often blackened by the fires of the natives or rung by the settler's ax, when they afford a grand

but dismal spectacle, as one speeds along in the train; in some countries square miles of country have been passed in which the forests have been rung preparatory to settlement, and in some cases for no obvious reason, as the land is unfit for occupation, and there stand those foreign monarchs of the forest like giant skeletons, sapless, lifeless-looking, dismal and forlorn in the midst, oftentimes, of a luxuriant undergrowth.

The trees are named usually according to the nature of their bark, which they shed instead of their leaves, such as stringy bark (*E. obliqua*), iron bark (*E. Sideroxylon*), blue gum (*E. Globulus*), peppermint tree (*E. amygdalina*).

The wood of some is very hard and durable, and so heavy as to sink in water. Many yield a kind of resin or gum, such as *E. resinifera* and *E. amygdalina*. A volatile oil of wonderful medicinal qualities is also produced from the leaves of various kinds, but more especially as that known from the *E. amygdalina*, which is the most productive, and yields nine-tenths of the oil of commerce, though not always placed on the market under its own name.

This arises from a certain amount of notoriety gained for the *E. Globulus* abroad, owing to the fact that it is the easiest of the species to acclimatize. As a matter of fact, however, there is scarcely any *E. Globulus* distilled in Australia. *E. mannifera* yields sweet secretions analogous to manna. *E. Gunnii* furnishes a liquid that ferments and forms a kind of beer. They all produce abundance of seed, which vegetates freely and becomes naturalized in various countries.

The *E. amygdalina* or giant eucalyptus, called "waugara" by the natives, is also known as the peppermint tree. This is one of the most remarkable and important of all the plants in the whole creation. Viewed in its marvelous height when standing forth in its full development of the slopes or within the glens of mountain forests, it represents probably the tallest of all the trees of the globe. Regarded as a hard wood tree of rapid growth, it ranks foremost, and contemplated in respect to its yield of volatile oil from its copious foliage, it is unsurpassed and perhaps unequaled by any tree in the world. These qualities have made it become generally known, and much through the exertions of Baron Von Mueller this tree is now being introduced abroad with good results in countries subject to neither severe frosts nor intense moist heat. It assumes under different climatic and geological conditions various forms. Thus, in the ravines of the cooler ranges it attains its greater height, combined with a perfect straightness of stem, while the bark strips so completely as to render the huge stem quite smooth and almost white.

In the more open country it is much smaller. Under these conditions it is called a "peppermint tree" in Victoria and Tasmania and a "messmate tree" in New South Wales.

In Victoria this tree often exceeds 400 feet in height. Such trees are found on the Black Spur, Upper Yarra Yarra and Upper Goulbourn. A fallen tree on the Dandenong ranges measured 420 feet. The length of the stem up to the first branch was 295 feet. The diameter of the stem where it was broken, 365 feet from the root, was three feet.

A still thicker tree in the same locality measured 53 feet in circumference three feet from the ground.

A tree near Mt. Wellington, Tasmania, has been found which measured 12 feet in diameter, 220 feet from the ground. Another tree was found 130 feet in circumference at the base. Within a square mile 100 trees could be counted with a circumference of 40 feet. At the foot of Mt. Baw Baw, Victoria, is found the highest of the giant trees of Australia. This monster is 471 feet high, and another on the Cape Otway ranges is 415 feet in height. The final height is sometimes attained by a single branch pushing skyward.

It is a grand picture to see a mass of enormous tall trees of this kind with stems of mast-like straightness and clear whiteness so close together in the forest as to allow them space only toward the summit to send their scanty branches and sparse foliage to the free light.

The distillation of the oil was first initiated by Baron von Mueller. *E. amygdalina* yields more oil than any of the other varieties, and is therefore almost solely employed for the purposes of distillation. It is also one of the best for subduing malarious effluvia in fever regions, although it does not grow abroad quite so well or quickly as *E. Globulus*.

The respective hygienic value of various trees may to some extent be judged by the percentage of oil in their leaves, as stated below:

	Per cent of oil.
<i>E. Amygdalina</i>	3.313
<i>E. Oleosa</i>	1.250
<i>E. Leucoxylon</i>	1.050
<i>E. Gonicalyx</i>	0.914
<i>E. Globulus</i>	0.719

The lesser quantity of oil in *E. Globulus* is compensated for by vigor of its growth and early copiousness of its foliage. It readily adapts itself to other climates, and hence abroad nearly all the varieties of the oil are known as *globulus*. During the last 20 years the blue gum has come into high repute as a sanitary tree. A high authority states that the sewage systems of large towns in warm climates would be simplified if each house had the evergreen gum tree in the back yard. The disinfecting and deodorizing virtues of the tree are unquestionable.

Flesh of any kind is as well preserved by eucalyptus as by creosote, while beef sprinkled with it will dry hard without putrefaction. It is fatal to bacteria and other micro-organisms. It may be injected into the veins and arteries of cadavers for purposes of preservation. It is also a good admixture in dressing gangrene.—Journal of American Medical Association.

THE Queen of the Hills mine at Broadford, Idaho, has been sold to an English company. It is understood that F. A. Thompson, the expert who examined the property, has a working capital of \$75,000 to draw upon, and an agreement to buy the Minnie Moore, if the Queen turns out satisfactorily.

State Ownership of Railways.

The *Engineering News*, in discussing this subject, says: "The State ownership of railways has been on trial in Europe for about 50 years. In 1849 the Prussian Government commenced the building of a line from Berlin to its eastern boundary, but the results were generally unfavorable and the ownership by the State would probably have been abandoned had not the military experience of the wars of 1866 and the Franco-Prussian war shown the defects of these existing conditions and the strategic advantages of a well-devised and operated system of railways. Under the new empire the commencement was made in extending and unifying means of communication, and in 1879 a bill was passed providing for the purchase by the State of all railways in private hands. From that time forward these roads were gradually acquired, until the Government now owns 15,530 miles out of the total 16,775 miles of railways in Prussia. In this State the general management of these roads has been at least financially successful, and according to recent information the revenue derived from them not only pays the interest on the railway debt, but also on the entire State debt, and for the fiscal year ending March 31, 1890, there was a surplus of over \$38,000,000 derived from this source. This was the maximum surplus, it is true, but for the year 1891-92 it was still about \$22,500,000. In addition to this successful operation nearly \$160,000,000 of the original railway debt has been extinguished. But, while this is a very favorable showing for Prussia, other European States have not fared so well. France, previous to 1842, had a few minor railways, but by the law of June 11, 1842, it was proposed to establish a vast network of lines under the following conditions: The State was to be responsible for the building of the road-bed, the structures necessary, and one-third of the land required for the right of way, and the departments and communes were to provide the rest of the land. The rails, ballast and material required to operate the roads were to be provided by the companies to whom the operation of the lines was to be leased. While this law has been modified by others passed since 1845, and private companies can now build and operate railways under restrictions imposed by the State, the French Government may still be said to control the railways in that country by a system of subsidies, and in the period of 1884-90 it paid out about \$74,000,000 for the privilege. At the end of 1883 the claims of the State against the railway companies amounted to over \$134,000,000. In other words, State ownership has been far from profitable under the system of subsidizing corporations practiced in France.

"Australian State railways pay at the most 2½ per cent, and Hungarian roads pay about 3 per cent. Italian State railways are in a still worse plight, for they paid only 1.63 per cent in 1892 on an investment of about \$900,000,000, and the tendency is toward still lower dividends under State management. In 1860, says the *Nuova Antologia*, with a capital account of \$109,200,000, the profits were about 3.6 per cent, but with a steady and rapid increase in the total amount invested the profits have as steadily diminished to the figures first given for 1892. A particularly bad omen for the future is the fact that in the same period (1860-1892) the operating expenses have increased from 53 to 70.4 per cent of the gross earnings. Prussia alone seems to have made her State-owned railways profitable. But Prussia built up her present railway system for strategic purposes mainly, and according to all accounts the administrative organization is defective and far from popular. The primary object of location, equipment and control is to meet the emergencies of war rather than to serve the conveniences of the people in time of peace, and that the system does pay such handsome returns as are credited to it can only be explained by the needs of a dense population accustomed to military rules and regulations and more prone to travel from place to place than are the people of France or Italy. In Italy particularly the cost of construction has been enormous, and the line along the coast of the Mediterranean, from the French frontier to the coast opposite Pisa and Florence, is almost one continuous line of tunnels. While the Prussian railways are excellently built and equipped after European standards, they have probably cost less per mile than those of Italy, Austria or Hungary owing to advantages of natural conformation. France subsidizes her railways purely for military purposes, and apparently is content to pay well for the possible advantages this control may some time return in an emergency. She takes no part in the operation and administration of the lines except in that which pertains to the maintenance of lines useful in war and in the general control of the accounts and records."

THE shipowners and sailors of this port have been at outs for a long time, and the Sailors' Union has had rather the best of it. The Shipowners' Association has established an office and made every effort to neutralize the effect of the union in securing men and controlling their actions. The owners want to govern the wages of sailors, and the board of directors have been busily at work devising a scheme to destroy once and for all the influence of the union. A new plan to be adopted by the Shipowners' Association aims to take control of the sailors absolutely out of the hands of the union and of the sailor boarding-house masters. If the scheme is carried into practical operation it will mean the expenditure of thousands of dollars and the engaging of a small army of employees. One of the first and most revolutionary of the innovations is the establishment of boarding-houses for the sailors, to be managed and conducted under the direction of the shipowners themselves. Houses will be rented and men employed. Fare and lodging will be furnished very cheaply, and the sailors will be given treatment they do not receive now. By the establishment of these houses the shipowners wish to secure control over the men not otherwise possible under the present or any other suggested system. As for the shipping of sailors, that is to be done only through the offices of the association, and men of all classes independent of union affiliations will

be accepted as long as they are capable of doing the work required. Branch offices for this part of the work will be placed in every port of moment on the coast. Sailor boarding-house keepers are as much interested in the plan as the Sailors' Union, as their occupation will be gone if the plan is adopted and supported. It will destroy their unenviable business and keep from them the blood-money and profits they have enjoyed for years.

Sprinkling Country Roads.

A committee of the Napa county Board of Supervisors recently visited Alameda, Santa Clara and San Mateo counties for the purpose of investigating methods and cost of sprinkling country roads. The committee found a more complete system in Santa Clara than elsewhere; the part of its report relative to that county is as follows:

"In this (Santa Clara) county, the roads sprinkled are either graveled or macadamized, and what are known as main roads. No public money is spent for sprinkling cross roads; but some are kept watered by subscription.

"Some of the roads near the city of San Jose are sprinkled on both sides; one side in the morning and the other in the afternoon or evening, thereby rendering that portion sprinkled in the morning in good condition for travel in the afternoon, and vice versa; thus keeping the roads smoother than when traveled immediately after being sprinkled.

"Seven hundred and fifty gallon tanks are generally used, and the spread of water from 14 to 16 feet; 750 gallons sprinkle from 1800 to 2000 feet, with team walking at the rate of about three miles an hour.

"Several kinds of pumps are used. One known as the John Stock 7-inch pump made in San Jose, and costs complete, \$60 less plunger rod (wood). Also the Byron Jackson centrifugal pump is used where the water is near the surface. The price of this pump we did not ascertain. Some wells are supplied with horse-power, and others, particularly the deep wells, with gasoline engines. The latter give better satisfaction than the horse-power.

"The wagons and tanks mostly used were built by the San Jose Agricultural Works and the Globe Carriage Works. Width of tire, 4 inches; cost of wagon and tank, \$250 each. They pay for man and team \$70 per month, and as the roads are sprinkled every day, they have steady employment throughout the dry season.

"In company with Supervisor Whitehurst we drove over that portion of the county lying west of San Jose and between Santa Clara, Saratoga and to near the base of the foothills on the Homestead road. This is known as the "dry section," or the part of the county where the wells are very deep, being from 150 to 250 feet in depth.

"On the Homestead road they have 5¼ miles of 2-inch pipe laid and 7 tanks of 5000 gallons capacity each. These tanks cost \$85 each, set up on frames 9 feet high. At the pumping station the water is raised 210 feet with a 6-horse power gasoline engine. The owner of the land dug the well and built the power house and tank therein; the county supplied the engine and all connections; also all material or supplies for engine. The party owning the land does the pumping for the use of water not needed by the county for sprinkling.

"Stevens creek road" is another road similarly managed. Depth of well, 225 feet. From this well about 16,000 gallons are taken daily, the owner of the land giving the use of the water without compensation. This plant has been run two seasons, and has not cost to exceed \$25 in repairs. The running expenses are \$2.25 per day. Length of pipe line, 5½ miles.

"The Saratoga road is piped for several miles, the water being raised from Campbell creek with four water mills. As these places are on high land near the base of the hills, on each road there is a gradual fall in the land from one tank to another, and a constant supply of water is obtained at much less cost to the county than on those roads where pumps are used at each station. It is intended to extend the pipe lines wherever practicable along these roads. The teams sprinkle about eight miles twice a day.

"The rate of taxation for road purposes in this county is 30 cents per \$100, and the amount of assessable property outside of incorporated cities, \$32,709,687. There is no general road fund, so each district, of which there are 17, takes care of its own roads. Weak or impoverished districts are assisted from the "current expense fund" on bridges and culverts.

"Where the county digs wells, the ground is leased for a term of years at a nominal rental of \$1 per year; about 45 feet square being sufficient for horse power; the well being dug on or near the line of the county road. We were informed that they never have any trouble getting the locations, as everybody wants the roads watered during the summer months and cheerfully pay the necessary increase of taxes for that purpose.

"We obtained the following prices on sprinkling wagons from the Studebaker Co. of San Francisco, viz:

"Spring wagon with 750-gallon tank, 3 inch tire, \$500; 4-inch tire, \$510. For steel tank, \$65 extra for 750 gallons, and \$45 extra for 600 gallon tank. Wagon with dead axle, 3-inch tire, 600-gallon tank, \$390.

"We also obtained the following quotations on iron pipe, viz: 2-inch black pipe, dipped, 11 cents per lineal foot delivered on board boat or cars; 10-inch riveted pipe, No. 14 Birmingham gauge, 80 cents per joint of two feet when used double, and \$1 per joint, same length with 6-inch collar riveted on one end.

"We would recommend that wherever practicable the system of gravitation be employed, and at all other stations requiring power to raise water, either a 2-horse-power, or small gasoline engine. If the latter, the same should be placed in charge of some person to insure its safety from destruction by evil-disposed parties.

"And we would further recommend that at present no roads be sprinkled at public expense except such as are known or recognized as main or leading county roads.

Respectfully submitted, G. W. DEWESE, C. M. BURGESS, W. A. TRUBODY, Committee.

The Pegleg Gold Mine a Myth.

For many years past there has been a tradition that Pegleg Smith, a forty-niner miner, once discovered a mine of fabulous richness on the Colorado desert. This mine has been described as being of solid gold and has been the object of innumerable expeditions and great loss of life. This was the object of the Breedlove party's expedition of last year, which ended in the death of all the participants.

Pegleg, who was widely known among the mining men, left a fairly good description of the landmarks and surroundings of his mine, but up to the present no one has ever been able to find anything to indicate there was any basis for his story.

A few months ago ex-Sheriff Martin Aguirre, Edward Mellus, F. C. Mellus and a well-known prospector named Michael Kirby organized an expedition to search for the mine, having obtained maps and descriptions which gave them a reasonable certainty of finding the bonanza. They got back to Los Angeles the other day, and have come to the conclusion that there is no such mine and that old Pegleg was a boss liar.

On the 17th of February last Mellus, in company with the parties previously named, started out with four horses and eight burros for the Colorado desert. They made for a little valley known as the Vallecitos, intending to make that their headquarters. The journey was a long and rough one. Their progress was barred with the almost impenetrable jungles of cacti and prickly mesquite plants, through which the treasure-hunters had to hew their way. The season was the rainy one, and the travelers often rode day and night through the pouring rain without finding shelter of any kind.

At last they reached the little valley and made their camp before commencing their march across the desert. After a short rest the burros were reladen and a start made for the three buttes which old Pegleg had described as being the locality in which he found the shining gold in heaps. Taking warning from the fate of the numerous prospectors who had lost their lives in the search, Mellus first saw to their water supply. Eight barrels, containing 11 gallons apiece, were packed on the burros and the journey was begun.

Not knowing exactly how long it would be before they reached the spring, the party determined to husband their water supply, and for four days the unfortunate burros plodded along in the burning sand without a drop of water.

From this spring, which is so carefully concealed by nature that a man may be parching with thirst within 50 feet of it and not discover its existence, they made their way to the three historical buttes along which old Pegleg had stated lay the gold. When they were reached the party at once commenced their search.

Days and days were passed in fruitless hunting. There were no signs of gold. All of Pegleg's landmarks were found, but not the precious metals. The only approach to it was a decomposed ledge running northwest and southeast. The ledge was honey-combed throughout and the prospectors dug to a depth of 20 feet, but when the dirt was washed not even a color could be found. All that remained were small garnets, none larger than a pin's head. The whole country for two miles around was thoroughly examined, and at last the disgusted treasure-seekers packed up and made their way back over the desert. Speaking to a reporter, Mr. Mellus said:

"I want to say, for the benefit of future prospectors, that there is and can be no such place as the Pegleg mine. I have looked up old Pegleg's record since my return, and, judging from the evidence of his friends and acquaintances, the old man was a blamed old liar. He has been the cause of many a good man losing his life, and I want to say right here that he was a fakir of the first water.

"The only foundation I can find for the story is that years ago miners in going to Fort Yuma used to take the old Butterfield route, which leads in the direction of the supposed Pegleg mine. The Cahuilla Indians used to make a practice of ambushing these miners and robbing them of their gold-dust. I know for a fact that 17 miners were shot down at one time. The Indians, afraid to bring back this dust at one time, used to bury it in the desert and account for their possession of it by stating they had found a wonderful mine, the locality of which, of course, they would not describe. In my opinion this is the source of the story of the wonderful Pegleg mine. Old Pegleg drew on his imagination, which was a good one. Why, he said he got lost and woke up one morning to find glittering lumps of gold all around him."

Mellus is confident that he reached the exact spot declared by Pegleg to be the site of his mine, and that his experience leaves no room for further credence in the old miner's story.

A CONTRACT was awarded in Los Angeles last week, which is regarded as a definite step toward the much-talked-of railroad from Los Angeles to Salt Lake City. The contract was given by the Los Angeles, Owens Valley and Utah Railroad Company to F. E. Green, of Los Angeles, to construct a line of railroad from Mojave to Independence, a distance of 160 miles. The cost will be about \$2,100,000, and the work will be done within nine months. The railroad company is an English syndicate, backed entirely by English capital. The same company is building a canal, 110 miles long, to run from 16 miles above Independence to the end of Indian Wells Valley. By means of this great irrigating main it is intended to open up for settlement 880,000 acres of land, and the new railroad will pass these lands.

A PARTY of gold-seekers sailed for British New Guinea by the Monowai this week. Among them are: Joseph McCauley, Michael Surley of Calaveras, J. Grogan and ex-Manager Houke of the Oakland Water Works. They take with them hydraulic machinery and apparatus and expect to be gone four years. The field is new and has been penetrated by none but McCauley and three others,

Scientific Progress.

The Five-Foot Glass Reflector.

Dr. Common recently put before the Royal Astronomical Society the details of his construction of a five-foot reflector. It will be convenient to summarize his results.

The first question that arises with respect to the construction of a reflector is, of course, as to the material of which it should be made. But this is not the time at which to consider it fully; and we will merely remark that, aside from the very well-known advantage peculiar to chemically-silvered glass, there are very important—all but equally important—reasons which could be assigned in favor of the employment of a metallic basis. Where the old-fashioned "speculum metal" is employed at all now, it ought naturally to receive a coating of dense and pure electro-deposited silver. But there is more to be said in favor of other metals, steel, for instance, for the substratum. The structure even of steel (which is in every sense of the word a somewhat refractory alloy) may be made sufficiently homogeneous to receive an exceedingly perfect surface finish, and by the Whitworth method sets of spherically curved surfaces (including planes of course), can be readily manufactured from such metal. If a sufficiently thin bright film of silver could be deposited on steel by chemical or electro-chemical means (which is a question that we shall return to later), then it could be removed by electro-chemical solution in weak cyanide of potassium, without injury to the subjacent metal. The last polish could scarcely be given by working similar metals one upon another; but the tendency to "tearing" might be reduced, as has before been suggested, by working pairs of surfaces coated with different metals upon one another. We will refer to this again, in considering the possibility of using a substance more reflective for actinism than is silver.

Of course, Dr. Common fixed on glass for the material of his great reflector, says the *Optician*. He was not under the necessity of troubling himself over its purely optical qualities; but homogeneity of structure was of the greatest importance for another reason. A focal length of twenty-eight feet seven inches is what was aimed at initially; and it was found that, immediately after two hours figuring, at 23 strokes a minute, with a 15-inch tool, the resin of which is tolerably hard, and the friction, consequently not nearly so much as it might have been, the excess of increase of temperature at the concave surface of the mirror was such as to lengthen the radius of curvature by no less than two inches. After a few hours' rest this great deformation had entirely disappeared. But no matter how slowly the process of grinding may be conducted, with such a material as glass some considerable deformation of this kind must be expected and allowed for. To the manufacturer of a number of large mirrors or lenses, from material of uniform quality, an examination of the rate and manner of development of such deformation as is here referred to would be of interest. Everything by which either the elasticity (the resistance to deflection) or the co-efficient of thermal expansion of the glass is caused to vary from place to place will be harmful in destroying the regularity of this unavoidable deformation, and therefore the symmetry of the surface under treatment.

The first intention of the designer of the five-foot mirror was to employ it in a Cassegrainian telescope, that is, of course, one in which the eyepiece is situated behind the center of the mirror, and the auxiliary small speculum is convex, so that the image which is presented to the eye is inverted. A hole of ten inches in diameter was therefore ordered in the center of the glass disc. While allowing that it is a very easy thing to be wise after the event, we suppose that most foundrymen would have been aware that to cast such a hole in the disc would not be conducive to homogeneity in the structure of the "metal." However, the hole was cast, instead of cut, as it should have been, in the first disc that was made; and in the result Dr. Common found that an irregularity in structure, and consequently in the deformation resulting from frictional heating, rendered hopeless any attempt to obtain the projection of a circular hole, placed at the center of curvature, otherwise than as a roughly elliptical image, the major axis of the ellipse lying always in a particular direction across the face of the mirror. Efforts finally made to correct the ellipticity by local polishing only resulting in general irregularity of figure. Possibly the disc might have been improved by raising it to a very high temperature (to the softening point) and re-annealing. Otherwise it was useless owing to the defect in structure which has been ex-

plained, and perhaps, also, as it is suggested owing to a condition of strain, induced by the fact that the disc, prior to grinding, had stood in an inclined position, i. e., resting at an angle against a wall, for about four years. It is to be hoped that ere long the elastic properties of glass will receive fuller investigation than has yet been accorded to these obscure but interesting and important matters.

It was next decided that a new disc of the present telescope should be ordered to be cast solid with the intention of mounting it as a Newtonian; and the grinding and figuring of this has been successfully accomplished. The finished mirror is in use in connection with a "flat" of 16 inches diameter, obtained from MM. Henry, of Paris.

A Physiological Effect of Cave Visiting.

Dr. Hovey's interesting account of a visit to the Mammoth Cave in March, published in *Science* for April 7, 1893, recalled a recent conversation with my father, Dr. C. Fayette Taylor, on the subject of the cave, which he visited in July, 1860. He was particularly struck with, and vividly describes, the physiological effects experienced on emerging from the cave. He made the usual long trip with some 15 companions, reaching upper air after a stay of about 12 hours under ground. On emerging, the sense of smell was intensified to such an extraordinary degree that most common objects, such as trees, plants, animals and even people had strong individual odors, mostly unpleasant. About half the party were strongly nauseated and vomited. One tree could easily be distinguished from another by its characteristic odor. This effect lasted about half an hour and then passed off. The guides told him that this was a usual experience. Dr. Hovey alludes to this effect of a sojourn in the cave in a lecture published in the *Bulletin of the American Geographical Society*, March 31, 1891, in the following words: "By contrast with the pure oxygenated air of the cave, the odors of the outside world, of the trees, grass, weeds and flowers, are strangely intensified and for many delicate natures overpowering." In a letter dated April 11, 1893, Dr. Hovey says: "I have always, or generally, been accustomed to rest at the entrance on emerging, for the reason that neglecting this precaution is apt to be followed by disagreeable consequences. I have known visitors to suffer from nausea and headaches by reason of a too sudden change from the peculiarly pure air of the cave to that of the outside world. The sense of smell is greatly intensified in almost every case."

I judge that this intensification of olfactory perceptions is due to the rarity of olfactory stimuli in the cave. On emergence, in accordance with a physiological law, the perceptive powers for these particular stimuli, having rested, are intensified, so that odors too delicate to make an impression under ordinary circumstances are powerfully felt. By the constant repetition of the ordinary olfactory stimuli, this effect passes off, and soon only the stronger odors are registered in consciousness. In other words, consciousness is mainly concerned with the registration of the contrast between the stimulus of the moment and a background of fused and undifferentiated impressions. Ordinarily, sensations are increased by more intense stimulation, but they may also be increased, as in the illustration just given, by varying the background so as to bring ordinary stimuli into stronger relief. That a similar effect has been intensified by heredity is illustrated by Dr. Hovey's remarks on the auditory sensitiveness of the cave fauna. He says in the lecture already referred to: "The tiny (blind) fish are colorless, having cartilage instead of bones, are viviparous, and are so sensitive that if a grain of sand should fall on the water they would dart away with rapidity. Blind crawfish are also found here, whitish, semi-transparent, with remarkably long antennae and more delicate in every way than those found in outside streams. These also are highly sensitive and not easily captured."—H. L. Taylor in *Science*.

THE relation of eye-color to health is an obscure question. It is said, for instance, that the health of the brunette type of eye is, as a rule, superior to that of a blonde type. Black eyes usually indicate good powers of physical endurance. Dark blue eyes are most common in persons of delicate, refined or effeminate nature, and generally show weak health. Light blue, and, much more, gray eyes, are most common in the hardy and active. With regard to diseases of the eye, brown or dark-colored are weaker or more susceptible of injury, from various causes, than gray or blue eyes. Light blue eyes are generally the most

powerful, and next to those are gray. The lighter the pupil the greater and longer-continued is the degree of tension the eye can sustain. The majority of first-class shots are men whose eyes are either blue or gray in color. Coloration must not be mistaken for cause. It is only a racial distinction indicative of the characteristics to which it is allied. Doubtless it is largely dependent on natural selection, certain colors having a fascination for certain types of individuals.—*Optician*.

Mechanical Progress.

Recent Examples of Electric Power Distribution.

At a meeting of the New England Cotton Manufacturers' Association, a paper was read by C. J. H. Woodbury, M. Am. Soc. C. E., describing recent developments in electric-power transmission and distribution. He stated that multiphase synchronous motors will be used in transmitting power from Sewall's Falls on the Merrimac river to Concord, N. H., a distance of about four miles. There is a total available power at this place of about 5000 h. p., and it is expected that about 3500 h. p. will be transmitted and utilized the coming summer.

At the new works of the Page Belting Co., at Concord, power is distributed electrically from dynamos in the old works. The whole cost of the electric apparatus was 20 per cent less than would have been required for a steam plant applied in the usual manner. The saving in power is also great. The largest size shafting in use in the new works is 2½ inches; but if the transmission had been solely by shafting and belts the main shaft would have been at least 5 inches in diameter. An incidental advantage of this method of power transmission is that there is not a single open hole in the floors of the new buildings. The openings for the steam pipes are packed around with asbestos.

At a new South Carolina cotton mill an electric motor drives the line shafting in each room. At the Crocker-Wheeler electric works, at Ampere, N. J., the heavier machine tools are driven by an attached motor, and, in place of using cone pulleys to regulate the speed, the motor itself is made to run at the speed desired. For the lighter tools one motor drives a line shaft from which power is taken in the usual way.

One of the most valuable applications of the electric motor is to the direct driving of calico-printing machines. At the Dunnell Print Works at Pawtucket a motor has been at work for 18 months driving a seven-roll printing machine. The uniformity of motion and the ease and smoothness with which the speed can be regulated have enabled the cloth to be printed at 50 per cent greater speed than by the old steam driven machine; and allowing for stoppages to change rolls, at least one-third greater output per machine is obtained. This gain on a machine whose first cost is about \$50,000 is an important one. The success of the application has been such that it is believed that in building a new print works it would be advisable to equip the whole establishment for electric-power transmission.

Oil Furnace for Blacksmith Shops.

For some time past Mr. E. B. Wall, superintendent of motive power of the southwest system of Pennsylvania lines west of Pittsburgh, has been using oil furnaces in his blacksmith shop at Columbus. These furnaces are 5 feet by 9 feet and are designed for heavy work, and have proved so successful, and well adapted for the work required of them, that others are being installed in other shops of the same system. One feature of this furnace that may surprise those who have not had much to do with oil furnaces of such size, is the absence of any stack or other means for carrying off the product of combustion. It has been found by actual experiment that when a stack is placed on such furnaces, the temperature cannot be maintained to as high a point as desired. Without a stack it is evident that the flames and products of combustion have a tendency to creep out wherever there is an opening. For this reason the doors in the front of the furnace are carefully fitted, and it is found necessary to protect the buck-staffs in the immediate vicinity of the doors, extending out a rib of firebrick from the front wall. These furnaces when first installed gave an economy of about 50 per cent over that of the coal furnaces, and an increased output of 25 per cent. The economy was not wholly due to the difference in the cost of fuel, a portion of it being accomplished by the reduction of labor, there being no wheeling and shoveling of coal and

ashes. While the increased output is maintained, the economy has, in a measure, fallen off, not due to the performance of the furnace itself, but because of the increase in the market value of oil since the furnaces were first installed.—*Am. Manufacturer*.

Properties of Aluminium.

Mr. A. E. Hunt, president of the Pittsburgh Reduction Co., says: The slight film of oxide which forms on aluminium exposed to the air is removed by immersion in a dilute solution of hydrofluoric acid, followed by rubbing with a camolite skin saturated with petroleum.

Aluminium loses (permanently) much of its rigidity, and (temporarily) a very large proportion of its tensile strength at a temperature of 400° to 500° F., becomes pasty at 1000° F., and melts at 1300° F. The longitudinal expansion of a 100-foot rod of aluminium is .00115 foot per degree F. Its conductivity for heat is, for hard-drawn wire, 38 per cent, and for annealed wire 38.9 per cent of that of silver. For electricity its conductivity is as high as 50 per cent of that of silver. Thus, one yard of annealed aluminium wire of .0325 inch diameter, at 14° C., has the resistance .05484 ohm.

As regularly put upon the market the metal contains less than one-fifth of one per cent of iron, and is free, therefore, from any appreciable magnetic polarity. By cold hammering, rolling, stamping, drawing, etc., the stiffness and hardness of the metal can be very much increased, as also by the addition of a few per cent of alloy. Quite a small percentage of silver, chromium, manganese, wolfram or titanium is sufficient to distinctly improve the color of aluminium by approximating it to that of silver. For cold-rolling aluminium the number of passes is about the same as for the treatment of soft steel. There is little difficulty in reducing the metal by rolling alone to a sheet of one two-thousandth of an inch thickness. Aluminium is in the best condition for rolling, etc., at a temperature of from 200° to 300° F.

The temperature of annealing is that at which a pine stick is charred by being drawn across the metal, or that at which a piece of iron appears just red in the dark. Of course the aluminium does not itself appear red hot at this temperature—a fact which our readers will have no difficulty in referring to in the high conductive power, and, therefore, low emissivity of the metal, and to the absence of any appreciable coating of oxide upon its surface.

According to Mr. Hunt, successful results can be obtained in soldering aluminium with an alloy of that metal and zinc, with pure zinc, or even spelter or common soft solder, provided that a flux "which has just been covered by letters patent" be employed.

Manganese Steel.

In a lecture recently delivered before the Franklin Institute, Mr. H. M. Howe described the properties of manganese steel. Among the points brought out by the lecturer was the fact that the strength and ductility of the material were both increased by hastening the cooling of the metal. In doing this in the case of manganese steel castings, however, it is necessary to take care that the rapid cooling does not cause cracks at re-entrant angles and other weak spots. In forging ingots of the steel the temperature, Mr. Howe says, should be raised gradually, as the metal conducts heat slowly. During forging the metal acts like a carbon steel containing 1.25 to 1.50 per cent of carbon, and requires heavier blows than most steels. It may be rolled hot into sheets .049 inch thick without special difficulty, and with proper precautions to as thin as .014-inch thick. Cold, it has been rolled still thinner, but requires frequent annealing. In machining it the hardest carbide or chrome steel should be used, Mueshet and other self-hardening steels being unsuitable. Light cuts and very slow feed are essential. As an estimate it takes four times as long to machine manganese steel as common carbon steel. At present the metal has been very successfully used for the pins of dredger buckets, as it resists abrasion in a remarkable manner, wearing only about one-sixth to one-eighth as fast as the best carbon steel. For armor plating preliminary trials with thin plates show that to offer the same resistance as a manganese steel plate a wrought-iron plate would have to be 75 per cent thicker. The metal has also been used for car wheels; 22 such have run on an average 168,653 miles before the first tiring. This figure, Mr. Howe says, is seven times the average mileage of chilled cast-iron wheels on this line, which is a particularly trying one owing to the frequent stops,

A NEW WIRE.—We learn from an exchange that a Connecticut manufacturing firm has brought forward a new resistance metal in wire, sheet or castings, which is regarded as a very important contribution to this class of material in electrical engineering. The wire resembles ordinary copper wire on the outside, has a pinkish-whitening at the surface of fracture, and is very strong without losing much ductility; the torsion test shows over 80 twists in six inches for an annealed wire, which still possesses 70,000 pounds tensile strength to the square inch, and hard-drawn wire is said to run to 100,000 pounds tensile strength, with about 40 twists in six inches. Combined with these favorable mechanical qualities it is claimed that the wire has the remarkable resistance of 35 times that of a copper wire with a temperature co-efficient of less than one-tenth that of German silver. By having the resistance lower than as above described, the tensile strength can be increased up to 140,000 pounds per square inch.

THE CHRISTIAN ENDEAVOR EXCURSION To the World's Fair!

Will leave on Tuesday, June 20th, under the management of the "Young People's" Society of Christian Endeavor, via Salt Lake, Manitou (Pike's Peak), and Denver. Special features as to stopovers and accommodations! Both Palace and Tourist Sleepers! Secure an itinerary of the trip.
W. A. BISSELL, O. P. A., 450 Market Street, (Chronicle Building), San Francisco, Cal.

Mining Superintendent

I am desirous of obtaining a position as Mining Superintendent. I am a graduate of the Columbia School of Mines, and have had 15 years practical experience as superintendent of mines and mills. Special experience as expert in concentration and amalgamation.

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us to offer advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S. F.

Certificate of Copartnership.

WE CERTIFY THAT WE CONSTITUTE A PARTNERSHIP transacting business in this State, its principal place of business is San Francisco, California. Its name is CONNOR & GRANT. The full names and respective places of residence of all its members are Samuel S. Connor, residing at San Francisco, California, Andrew S. Grant, residing at San Francisco, California.

SAMUEL S. CONNOR [SEAL]
ANDREW S. GRANT. [SEAL]

July 12, 1890.

State of California, City and County of San Francisco.—On this 12th day of July, in the year one thousand eight hundred and ninety, before me, George T. Knox, a Notary Public in and for said City and County, duly commissioned and sworn, personally appeared Samuel S. Connor and Andrew S. Grant, known to me to be the persons described in, whose names are subscribed to, and who executed the within and annexed instrument, and they acknowledged to me that they executed the same.

In witness whereof, I have hereunto set my hand and affixed my Official Seal, the day and year in this Certificate first above written.

[Notarial Seal]

GEORGE T. KNOX,
Notary Public.

I, M. C. HALEY, County Clerk of the City and County of San Francisco, State of California, and ex-officio Clerk of the Superior Court in and for said City and County, hereby certify the foregoing to be a full, true and correct copy of the original Certificate of Copartnership of Samuel S. Connor and Andrew S. Grant, filed in my office on the 12th day of July, A. D. 1890.

Attest my hand and seal of said Court, this 20th day of April, A. D. 1898

M. C. HALEY, Clerk.

By Wm. B. Lyman, Deputy Clerk.

[Seal of Superior Court.]

ARTIFICIAL LEGS AND ARMS

WITH RUBBER FEET AND HANDS.

It is not unusual to see an engineer with hand on the throttle, or a conductor, brakeman, fireman,

carpenter, mason, miner, in fact men of every vocation, wearing one or two artificial legs with rubber feet, Marks' Patents, and performing as much labor as men in possession of all their natural members. Over 14,000 artificial limbs of Marks' Patents in use. Purchased by the U.S. and many foreign governments. One-half of the limbs furnished by us are made from measurements without our seeing the wearers. Not guaranteed. A treatise of 430 pages, with 260 illustrations and a formula for measuring sent free. Address,

A. A. MARKS, 701 Broadway, New York.

Electricity.

The Electric Railway Trolley.

Another broad patent for a gigantic monopoly has recently been issued by the Patent Office. This is a patent for the invention of the late Chas. J. Van Depoele, who was a well-known electrician. The patent was applied for in 1887, but other inventors claimed substantially the same thing at the same time, which led to the taking of evidence from the several claimants to determine who was the original and first inventor. These proceedings, termed interference proceedings, have recently been brought to a close, and the Patent Office awards the patent to the administrator of Dr. Van Depoele, the inventor himself having passed away. The patent has been purchased by the Thomson-Houston Electric Co., and if its validity is sustained, of which there is at present no reason to doubt, the above company will enjoy a far-reaching monopoly, covering substantially all the electric railways in the country and the plants therewith connected. Over 6000 miles of these railways are now in operation, and they are being extended rapidly in all directions. This monopoly has 17 years to run. It is probably of greater importance to the public and of more value to its owners than the telephone invention.

The claims of the Van Depoele patent are very broad and comprehensive. The principal claims are as follows:

The combination of a car, an overhead conductor above the car, an upwardly extending and laterally movable arm carried by the car and having its upper end free, and a contact device carried by the arm at its free end, and making underneath contact with the conductor.

The combination of a car, an overhead conductor above the car, a contact device making underneath contact with the conductor, and an arm on the car movable on both a vertical and transverse axis and carrying the contact device.

In an electric railway the combination of a car, a conductor suspended above the line of travel of the car, a rearwardly extending arm pivotally supported on top of the car so as to swing laterally and provided at its outer end with a contact device engaging the under side of the suspended conductor, and a tension spring for maintaining an upward pressure contact with the conductor, substantially as described.—Scientific American.

A Good Profession.

"I consider electrical engineering a very good profession for a young man, but it is a profession which requires considerable exercise of intellect. On account of the fascination connected with the study of electricity the profession draws to its ranks an intelligent class of young men.

"Of course, it is probably true that the majority of young men who enter the profession are more or less enthusiastic, but in these days a knowledge of electrical engineering has become almost indispensable for engineers in general.

"Nearly every engineer at the present time follows with great interest its developments. And it is the same with the medical profession, for physicians are realizing more and more that electricity will ply a still larger part than it does in the cure of disease.

"For instance, a great amount of electrical energy may be sent into the body by means of high currents, because the energy is dissipated laterally from the body and is not passed through it in a direct manner as it is when a current of low frequency is used. The feeling produced is somewhat different.

"I have also noted the importance of one being prepared for the shock. If you are prepared the effect on the nerves is not nearly as great as when you are not prepared. With these high alternations one feels but little pain in the central portion of the body. A remarkable feature of such high currents is that you feel a burn the moment your hand touches the wire, but beyond that the feeling is scarcely noticeable. I have received currents as high as 300,000 volts, an amount which, if received in any other way, would instantly kill."—Nikola Tesla.

STATION VOLTMETERS.—Perhaps the most recent application of photography which has come to play quite an important part in scientific work is a registering device for recording a continuous reading of station voltmeters. The apparatus is described as follows: An incandescent lamp is arranged so that the rays of light which emanate from the glowing filament are directed in a parallel sense upon a narrow slit, before which is

placed the needle of the voltmeter. Obviously, in moving across this illuminated slit, the needle obscures the light and the shadow is then recorded upon the sensitized paper as a white image upon a dark ground (the image of the illuminated slit). By an ordinary clockwork mechanism the sensitized paper, which is rolled upon a drum, is caused to move at a regular rate, and the intervals of time are recorded upon it photographically at the same time as it receives the shadows of the moving needle.

Propelling Canal Boats by Electricity.

About two months ago the New York Legislature appropriated \$10,000 to defray the expense of conducting experiments in propelling canal boats by electricity. At the present time several projects are under consideration and it is hoped that a practical scheme will be evolved that will prove commercially successful. One of the most promising plans submitted is that of a Buffalo engineer, who has worked out the details of a very elaborate system. This scheme in some respects follows the general line of the trolley system of street railways. Power plants will be constructed at regular intervals along the route of the canal, from which current will be supplied by an overhead trolley system to the boats. Three trolley wires will be suspended over the head of the canal and these will be so adjusted that allowance will be made for a boat departing from its regular course. This, of course, would be necessary in order to allow boats to pass each other and make turns and stops at docks. In the stern of the boat will be placed a motor to drive the screw which will propel the boat.

The same considerations which have led to the substitution of the electric motor for animals upon street railways apply to the propulsion of canal boats by electricity. At the present time, it is the practice to provide accommodations for horses upon the boats, and this means that much valuable space is devoted to stalls and feed-hins which could be utilized to advantage. But much more important than mere commercial advantages are the sanitary considerations which should influence the legislature in adopting an electric system. There is no doubt that the presence of horses and mules on the boats is not conducive to good health, and the practice of throwing refuse from canal boats into the sluggish stream is reprehensible. Under the present conditions, however, it is certainly almost impossible to enforce sanitary regulations. New York has a fine waterway in the Erie canal which, if equipped electrically, would be greatly enhanced in value, and would prove an important factor in regulating freight rates. It is to be hoped that the present movement will be followed up until the proposed system shall have been given a fair trial.—Western Electrician.

ACCUMULATOR TRACTION.—Mr. Raymond Schiller, in an article in the *Elek. Zeitschrift*, April 7th, on the calculation of accumulators for street railways, develops a simple formula for calculating the starting power per ton weight of car. He advocates using a battery having a capacity sufficient for two trips, but charging it every single trip; instead of moving the batteries into and out of the car he recommends having as many cars as there are batteries, as the handling of the cells is injurious for the battery. The extra expense of the cars, he claims, is not greater than in the installation for handling the cells in the other case. The battery should be in a separate car, which is coupled to the motor car, the passengers being in the battery car. (But he then loses the advantages of the weight of the battery and the passengers for increasing the adherence at starting.) To prevent the battery from being discharged too rapidly, he recommends putting a resistance in circuit in preference to a fusible cut-out. He thinks it better still to use a battery of high internal resistance, in order to avoid a too great discharge current. In this case higher voltage than too would be used, which, he says, is no disadvantage, as one can then use a mixed system, namely, running the cars with accumulators through the heart of a city and with overhead trolley lines in the outskirts, the accumulator car being uncoupled at the beginning of the overhead line, where the battery is then charged. Such a mixed system, he thinks, is more likely to solve the problem of traction in the cities, and he therefore recommends accumulator manufacturers to make trials with high-tension batteries.

To extract ink from cotton, silk, or woollen goods, dip the spots in spirits of turpentine, and let it remain for several hours; then rub thoroughly between the hands, and it will all disappear without changing either the color or texture of the fabric.

Useful Information.

Future Timber Supply.

The question of our future timber supply and the annual waste from fire is discussed in a special circular sent out to the lumbermen of the United States by Mr. Fernow, Chief of the Forestry Division of the United States Department of Agriculture. As to the demand for timber, Mr. Fernow figures from the census and other returns that we annually use over 22,000,000,000 cubic feet of wood, or about 350 cubic feet per capita. Of this enormous amount over 4,000,000,000 cubic feet of the best material is converted into lumber; railroad construction consumes about 5,000,000,000 cubic feet, and fencing takes about the same; but by far the larger consumption is for firewood. An uncertain amount is burned every year by forest fires, which rage in the western mountains especially, and the total of wood annually disposed of in some way is probably near 25,000,000,000 cubic feet. The area of the United States covered with wood growth is less than 500,000,000 acres, and for the last three decades an increase of about 30 per cent in consumption is indicated for each decade. With this showing, as nearly accurate as the available statistics can make it, it is well to estimate how long this supply will meet an ever-increasing demand. From the careful records of the German government and those of private forests in Europe, it is known that the average annual growth of wood per acre does not exceed 55 cubic feet, and this includes branches and smaller dimensions down to three inch diameter, wood which is not used in this country. If we confine ourselves to the production of sizes of timber utilized by our wood cutters, says Mr. Fernow, our timber at the age of 125 years would not average in growth more than 35 cubic feet per year, so that our present acreage, even if well stocked and well guarded and managed, would not produce our present annual consumption. And as to our total supply, the most extravagant assumption that can be made, even for the enormous Pacific coast forests, is an average of 10,000 feet B. M. now standing on every acre of our wooded territory. With this assumption our standing timber would be exhausted in not much over 100 years; or the time it takes to produce a good-sized sawlog. Most of the timber we are now cutting is over 200 years old, and for some timbers the seed is even now relatively in sight. This is the case for white pine, walnut, yellow poplar and ash.

The remedies suggested are the more careful and thorough utilization of our timber products and especially the prevention of unnecessary waste. The most harmful among the latter are forest fires, which not only destroy or deteriorate in value enormous quantities of timber annually, but also render the soil barren by burning up the leaf mold and seedlings and replace valuable timber by scrub and inferior vegetation.

The Daily Bath.

A daily bath is not only a luxury, it is a necessity. A plunge bath is not within the compass of every one. A sponge bath is always feasible. This may be taken with no appliances beyond the bowl of water, the sponge or wash-cloth, the soap and towel. It is more easily managed with the aid of a large foot-tub, in which the bather may stand while she uses the sponge.

The temperature of the bath is a mooted question upon which doctor and patient disagree. To some persons there is nothing more bracing and invigorating than a cold plunge, while others do not recover for hours from the chill such a bath gives. Certain physicians recommend a very hot bath and assert that it is stimulating in its after effects as is the cold plunge, and less likely to produce ill effects. Nearly all unite in declaring immersion in the tepid bath relaxing, and thus detrimental to health.

The question is one that each bather must settle for herself. What suits one may be positively harmful to another. Certain it is that the hot or warm bath is more cleansing than cold water. The sudden chill of the latter closes the pores and prevents the escape of the effete matter it is the object of the bath to remove. The woman who takes a cold plunge for its after effects should first sponge herself off in warm water and achieve cleanliness before she indulges herself in her "bracer."

Only the best soap should be used in bathing, and many women do not use soap at all, preferring the hags of bran, oatmeal or almond-meal, which may be procured from druggists or other dealers in toilet articles. By the use of these hags the skin is cleansed and softened delightfully. A

greasy skin is sometimes benefited by the addition to the bath of one or two tablespoonfuls of household ammonia. Borax is also excellent for this purpose.

The hand may be employed in scrubbing the person, and may either be bare or covered with a bathing glove of rough Turkish towelling by those who prefer this method to the use of a sponge or wash-cloth. A vigorous rubbing assists the action of the skin.

Whoever feels a chilly sensation after a warm plunge, and experiences difficulty in regaining her normal temperature, should try the experiment of sponging herself off with cold water when she leaves the hot bath, and see if the slight shock will not tone up the skin and prevent any subsequent chill.

The beneficial effect of a bath is greatly heightened by a hard rubbing after leaving it. A rather coarse or rough Turkish towel should be used, and the friction should not be stopped when the moisture has been removed, but continued until the body is in a glow from head to foot. This operation will only require a few moments, and it is well worth the trouble.—Harper's Bazar.

Drilling Holes in Glass.

Julian A. Moses, in "Letters from a Laboratory" in the *Electrical Review*, says: Having had quite recently to drill a number of holes about three-eighths of an inch in diameter in a plate of glass, it became necessary to devise some means whereby this could be easily, rapidly and satisfactorily accomplished. It is, as is everything else, due care must be observed. This very brittle substance will not bear much rough usage, and it is only by gradual means and the removal of exceedingly small particles at comparatively long intervals that will enable the operator to work against the continual threatened danger of exceeding the limit of the allowed strain.

I have heard of holes being punctured at a desired point by the passage of a spark from a powerful battery of Leyden jars; but this appears a rather uncertain means to be employed, for there are too many opposing elements to success, such as the variable thickness of the glass, the necessity for absolute elimination of all superficial moisture, imperfections in the glass and consequent passage of the spark through the path of least resistance, to warrant its use. While the process is rapid, it is extremely uncertain and in the end but a small puncture is obtained. Slow grinding by a rapidly revolving copper or soft brass tube, with suitable abrasive materials, is the safest method.

Notwithstanding the apparent simplicity of the operation, there is a continual liability of cracking the glass from excessive pressure. The device to which I have referred is constructed as follows:

A shallow iron or tin-plate pan should be provided and a layer of rubber cloth put upon the bottom. This elastic material upon which the glass is placed serves as a medium to prevent vibrations, as a resistance to the pressure of the drill and is capable of withstanding the strain and equalizing and uniformly distributing the applied force, thus affording a minimum chance for breakage. Over the glass should be poured sufficient cold water to cover it to about the depth of one-quarter of an inch. Rather coarse emery should be used and the bottom of the revolving copper tube kept continually supplied by means of a feather which has been dipped into the emery. Move the revolving drill up and down about once per second to present new and fresh cutting surfaces and in a short time a circular piece may be removed from the glass, leaving the hole even and smooth. To avoid all possible danger of the glass splitting before the perforation is complete it is best to grind from both sides, allowing the final separation to take place in the middle of the thickness of the glass plate.

As the end of the grinder approaches the opposite surface of the glass the pressure must be gradually diminished, otherwise the great strain obtained, due to the additional friction, will be liable to split the glass. These radial fractures are often in most peculiar shape, and will in a measure determine the quality of the glass.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 60-horsepower Engine and 45-horsepower Boiler with Ore-crusher and other machinery, Mill Scales, As-saying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESPIE, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-braker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

...SOLE MANUFACTURERS OF...

KENDALL'S PATENT
QUARTZ MILLS.

Having renewed our contract on more advantageous
terms with Mr. S. Kendall for the manufacture of his
Patent Quartz Mill, we are enabled to offer these mills at
GREATLY REDUCED PRICES. Having made and sold
these mills for the past 14 years, we know their merits,
and know that they have given perfect satisfaction to pur-
chasers, as numbers of commendatory testimonials prove.
We feel confident, therefore, that at the prices we are now
prepared to offer them, there is placed within the reach of
all a light, cheap, and durable mill that will do all that is
claimed for it and give entire satisfaction.

BOOKS ON ASSAYING.

BY C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes thereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt. It
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Obarging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assay; Examples of Dressing; The Melting in
Crucibles; Scorchification; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Conceal Metal; Assay of Roasted Ore for Solubility; To
Assay a Sample; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth, 1889. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—JUST OUT.
Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion,
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Oxy-Lucac's
Method; Volhard's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel
and Cobalt; Chromium; Bismuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.

Price, postpaid, \$1.75. Sold by **DEWEY PUBLISHING**
CO., Publishers No. 220 Market St., San Francisco.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner..... \$550, f. o. b.
 " " " Improved Belt Frue Vanner..... 800, f. o. b.
 " 6-foot " Plain Belt Frue Vanner..... 800, f. o. b.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Calaveras Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (30 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for TWELVE MONTHS. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 30 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six foot Frue Vanner too highly, and it is the only table that I would have in my mill.
 C. J. CLARK, Gen'l Supt.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

H. J. SUMMERHAYES, Successor to Adams & Carter, Agent for the FRUE ORE CONCENTRATOR.
 No. 132 Market Street. - - San Francisco, Cal.

THE WOODBURY ORE CONCENTRATOR WITH IMPROVED BELTS

Was awarded the Highest (Bronze Medal) Premium at Mechanics' Institute, 1890 and 1891. MORE THAN DOUBLE THE CAPACITY with one-half less power and occupying less than one-half the space of any other concentrator. Built of Best Steel and Wrought Iron. Strong and Durable.

PRICE, \$575, f. o. b.

Send for Catalogue and Testimonials. The annexed cut shows the belt in its improved form, which consists of corrugated edges, to form an expanding top edge.

THE SAN JACINTO ESTATE—Office of the General Manager. OAKLAND, Oct. 30, 1891.
 GEO. E. WOODBURY, ESQ.—Dear Sir: In reply to yours of the 27th inst., respecting the working and efficiency of the "Woodbury" Concentrator placed in our Works by you, I am pleased to inform you that it is giving entire satisfaction; it has a much greater capacity than any other machine, and is doing fully one-third more work, with the concentrates equally clean, as from either of the machines at work here.
 (Copy) Yours faithfully, S. HARRIS, Manager.
 THE SAN JACINTO ESTATE, LIMITED—Office of General Representative, P. O. address, South Riverside, San Bernardino County.
 OAKLAND, February 17, 1892.
 GEO. E. WOODBURY—Your letter of inquiry about your concentrator came to hand in due course. Your machine is doing well, the motion is all right, and the machine is giving entire satisfaction. Yours faithfully S. HARRIS.

PATENTED
 Aug. 13, 1890.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

PLYMOUTH.—Cor. Amador Ledger, May 24: The hotels at this place have been pretty well crowded with mining men from different places the past week; some from San Francisco, some from New York, and various other places; some looking after acquired interest, others looking for chances for investment. E. Montgomery, Hayward's general manager, I suppose, has been looking over the vast estate that the latter is interested in in this county; also Mr. Cross, whom I understand is the general manager of the Hobart estate. I heard of one sale effected this last week. Messrs. Hynde, Adsu & Mathew made a sale of their New London property to Mr. Colman, of San Francisco. I did not learn the terms or figures. I hope these parties have bought a good thing, and that they may have better success than did Messrs. Ballard & Martin. Mr. Colman says that it is the intention of the new company to put up the necessary machinery to work the mine immediately. This same company, I understand, is trying to secure other properties in the neighborhood. The Bay State has now been running its new hoist for two days, and, as I predicted, it has proven a model machine, and gives unbounded satisfaction. They are lowering the water very fast in the mine, and Mr. Griffith, the foreman, says he thinks that, within two or three more days, with no intervening accident, he will see the long-looked-for bottom. I was talking with one of the employees of the Pioneer mine last evening, and he informed me that in the past week in mining the south level they struck some very rich ore, which shows plenty of free gold. He thinks it is high grade, and also states that everything looks well for a fine, large chute of ore. A. M. Vaughn, in doing his assessment work on the extension of the Canaanian, has developed one of the finest ledges that has ever been uncovered in this vicinity. Mining experts that have examined it pronounce it the chief. He was offered \$5000 for the prospect, spot cash, but refused it. I have no report from Smith or Ford this week, but presume everything to be working smoothly. The Wild & Wheeler mill is hammering away, and I have no doubt but that it is with results satisfactory to the company.

MIDDLE BAR DISTRICT.—Amador Ledger, May 26: Our reporter visited Middle Bar mining district last Tuesday in company with Supt. J. H. Tibbitts, of the Albany mine.

THE ALBANY.—The Albany Gold Mining Co. was organized last November, with a capital stock of \$1,000,000. The company owns one mile of land in Middle Bar district. The boundary begins about two miles south of Jackson and extends down the Mokelumne river. There are five separate claims on the property, to-wit, the Hollywood, the Elephen-gine, the Astoria, the Middle Bar and the Littlefield. Each claim is 1500 feet in length and 800 feet in width. At the Littlefield claim a tunnel is being run through the west-country rock. The tunnel is now in 150 feet, and surface measurements indicate that the ledge will be encountered at a distance of about 160 feet. The ledge dips east, so that they may have to go in a little further. The formation of the face of the tunnel, however, indicates that the ledge is not far off. The croppings prospect well. At the Astoria claim a tunnel is being run into the east-country rock. It is now in 185 feet and it is expected to reach the ledge at a distance of 200 feet. The formation is very hard in both this and the Littlefield tunnels, and not more than four or five feet can be run in a week. The Astoria tunnel is high upon the bank of the river, so that a splendid dumping ground is afforded. The Middle Bar claim adjoins the Littlefield on the south and is on the north bank of the Mokelumne. There is a two-compartment shaft down 70 feet, well timbered. There are two parallel ledges, and the croppings indicate that they are from 10 to 20 feet wide. They are about 100 feet apart. The croppings prospect from \$5 to \$7 per ton, while the ledge matter in the bottom of the shaft assays \$10. The croppings are well charged with sulphurets. These veins run north and south, with a dip of about 65 degrees to the east. There is a great fissure between the walls. Supt. Tibbitts says that as soon as the necessary working material can be delivered the Middle Bar shaft will be cleared of water, of which there is about 30 feet. Some kind of surface plant will be erected for that purpose. Mr. Tibbitts is prosecuting work on a systematic and economical basis, and as soon as he becomes satisfied that the Albany Co. has a good property, of which there is little doubt, developments will be begun on a more extensive scale.

THE HARDENBURG.—At the Hardenburg work is being prosecuted vigorously, with three shifts of three men each. The shaft is down 650 feet and it is proposed to sink 800 feet before opening up levels. The miners go down about 50 feet a month. The quartz now in the bottom of the shaft prospects well.

THE FARRALL.—At the Farrell mine, which lies south of the Hardenburg and the Albany, the tunnel is being extended in on the ledge. Three shifts of two hands each are being worked. On the dump there are several tons of rich ore, which will be shipped to Selby & Co., of San Francisco.

COL. ROBINSON'S MINE.—Col. Robinson, just across the river about half a mile, has begun operations by cleaning out the tunnel and extending it.

A NEW MILL.—Just west of Col. Robinson's

mine, in Gwin Mine gulch, the Giant Powder Co., of San Francisco, is erecting a five-stamp mill, a hoarding-house and sleeping apartments. The mill is second-hand, having been brought down from Murphy's. Twenty names are on the pay-roll of this mine.

GREAT ACTIVITY.—There is great activity in Middle Bar district, and every mine is being worked on a legitimate, systematic and economical basis. The men who have charge of these various properties have had long experience in mining and are going ahead in a business-like manner. There is not a "wild-cat" scheme in the district. The day is not far distant when Middle Bar district will become one of the famous gold-producing sections of Amador county.

IN OTHER SECTIONS.—The Thomas-Bothwell mine, of which our Forest Home correspondent has spoken of late, is a gravel claim, on the creek about two miles below Forest Home, and is on the land of Mrs. Ritter, of Sutter Creek. Thomas and Bothwell commenced work there about three months ago, tearing down the banks of the creek with three monitors, using water from the Ritter ditch, which they have leased. As the bank was torn away it was washed through a sluice, about \$4000 being cleaned up. The bed of the creek was so flat, however, that the tailings soon obstructed the flow of water and some method had to be devised by which a flow could be obtained. This, for a time, was accomplished by elevating the sluice boxes, but throwing the bedrock scrapings into elevated sluices with shovels proved to be an expensive operation; so the company has decided to put in a hydraulic elevator to throw the washings up about 20 feet and into the sluices, and also to put in a tailings elevator to carry away the accumulated material which stops the flow of water. In this work they will use about 1400 inches of water and employ between 20 and 30 men. The Kennedy people have struck the ledge at the 1650-foot level, at about 25 feet from the shaft. They had to crosscut 50 feet at the 1750-foot level. The rock they have encountered at that point looks better than any they have ever mined, and, in consequence, the stockholders of the Kennedy are rejoicing.

El Dorado.

DRIFT DIGGINGS.—Georgetown Gazette, May 25: The old mountaineer, A. J. Wilton of Kentucky Flat, was down yesterday. He gave a very satisfactory account of himself and the drift diggings of that volcanic-capped district. Mr. Wilton is looking as hardy and cheerful as ever we saw him. It is generally known among his acquaintances that he grows as fine potatoes and apples as the mountain produce, and that lying beneath this agricultural land from 50 to 200 feet is his drift gravel diggings. Just to show how his potato patch has panned out this season he brought from his pocket a handful of nuggets, ranging from \$3 to \$10. This was confidential; but such a sight is too good to keep, and our readers must know it.

Oro Fino.—El Dorado Republican, May 25: Alvinza Hayward and C. D. Lane have bought the Oro Fino mine and bonded quite an extent of mining property adjacent thereto. They are moving machinery upon the property from Angels Camp and will sink the shaft to the depth of at least a thousand feet. The fact that Hayward, who is one of the most successful and business-like miners on the Pacific Coast, has taken hold of this property will greatly encourage mining developments in that part of the county.

PROMISING.—Placerville Democrat, May 27: The mining outlook in El Dorado county has not been so promising for many years as it is at the present time. Many changes are taking place by which mines are falling into the hands of capitalists who are able to make developments. Mr. Alvinza Hayward has purchased the Oro Fino mine at French creek and is preparing to work that property on a large scale. We get information from reliable authority that the Starlight mine in the same district is to be started at an early day upon a basis that will assure success. An important event in the interest of mining in this county is the opening up of the old Tullis mine in El Dorado mining district, joining the celebrated Church mine on the north. This mine was opened in 1852 by Mr. Tullis, who, in a primitive way, took out considerable gold, afterward leasing it to a lot of Spaniards who mined the ore and packed it to an arrastre, taking out a large amount of gold, but just how much was never known; and, as the lease was for a percentage on products, it did not prove satisfactory. The property in 1857 passed into the possession of Mr. Caldwell, who sunk several shafts, one of which was about 150 feet deep. From this excavation alone he took out over \$14,000. Mr. Caldwell died, and the mine lay idle for several years, but was finally re-located by Mr. H. F. Tracy of El Dorado, resulting in several years litigation. Mr. Tracy finally obtained title. An arrangement was then made between Mr. Tracy and Mr. J. S. Finch, by which the latter was to do a stipulated amount of work on the mine for a half interest. Seven shafts have been sunk on the vein ranging from 22 to 200 feet in depth, 100 feet apart, showing a continuous ore body from 2 1/2 to 4 feet wide, for a distance of 800 feet. Mr. Finch will now commence a tunnel to open the mine to a vertical depth of 540 feet, which will be much more on an angle of the vein. Two power drills will at once be put to work, and it is expected that within three months the mine will be so far advanced as to justify the construction of a mill. A mill-site has been located conveniently below the mouth of the tunnel, where 400 feet of pressure can be had for water-power. Eleven tons of ore taken from the 200-foot shaft yielded, when crushed at a mill to which it was hauled, \$26.50 per ton. This mine is on a line with, and in the same formation as, the Keystone, Plymouth Consolidated, Springfield, Church and

other prominent mines, and there is every reason to believe, from its present showing, that it is as good as its neighbors. It is gratifying to know that this old mine, which has been a bone of contention for over 40 years, is to be once more started up under the most favorable auspices. The Big Sandy mine recently made a test run which proved entirely satisfactory. The Blue Bird mine, near Sand Mountain, is showing exceedingly well, and a mill is now being erected there, which is expected to be running in about 30 days.

Inyo.

BIO PINE.—Cor. Inyo Register, May 27: The mining interest and confidence in the mineral resources of Inyo have no more faithful advocates than the dwellers of the hamlet. Your correspondent visited some locations at Lead Canyon a couple of times within the past ten days, the first time in company with Geo. L. Cornell of Big Pine and M. D. Ratcliff of Silt Lake. Mr. Ratcliff is an experienced geologist, thorough mineralogist and practical miner. We found the latter gentleman in company with Wm. A. Sanger, of the east side, at Waucoha, they having inspected several claims in which Mr. Sanger is interested, lying between the Sanger ranch and Waucoha springs. Mr. Ratcliff reports seeing some fair chloriding chances in this belt; and predicts that several claims visited will be successfully worked in the near future. The principal claims in the Lead Canyon belt are the Bullion, located by Geo. L. Cornell, ex-Sheriff J. R. Eldred and S. H. Spratt. These parties have two other claims in company. J. N. Munro and R. W. Thomas have some promising claims in this section. Mr. Ratcliff expressed himself as well pleased with the appearance of the ore, the nature of the formation and the natural conditions of the belt. There has been little work done except upon one claim, the New Moon. John Erwin and C. F. Fuller of the prospecting firm of Fuller & Melone several years ago drove a good working tunnel in the ledge matter, encountering small quantities of lead carrying from 12 to 120 ounces of silver, the lead running as high as 70 per cent. Many thousands of tons of ore are now at the mouth of this tunnel which can be worked at a small profit by processes of reduction of late discovery. The south extension of the Bullion shows some fine-appearing carbonate ore, one of the locators of which, Mr. J. N. Munro, intends having the mines developed in the near future. There is excellent forage in this country for horses, and an abundance of wood and water for reducing ore by steam power. Quite a number of old-timers have always claimed that the top indications for a good lead camp are much better in Lead Canyon than at Cerro Gordo, and have predicted that "some day" this section would rival the output of the latter camp in its "whooping" time.

Kern.

THE BRIGHT STAR MINE.—Oakland Times, June 1: The St. Louis and San Francisco parties who recently recommenced work on the Bright Star mine on Pinta mountain have pumped all the water out of the old workings and retimbered the old shaft, which is about 330 feet in depth. It will be remembered that in times past this mine yielded a great deal of gold. But it was worked at a time when all expenses were very much greater than now, and upon encountering a layer of poor ground in the lower levels the mine was shut down. It is now reported that the present owners have found the old pay chute in the bottom level, or else a new one. At any event it is a paying one, and striking it at such a depth is almost certain assurance of renewed prosperity. Deirich Babben, who was one of the owners of the property in its palmier days, has been engaged as underground foreman on account of his familiarity with the former workings. If the pay chute just discovered proves to be permanent it will do much toward reviving the general mining interests of Kern.

Mono.

THE BOUTA CON.—Miner, May 27: During the past week south drift, 200-foot level, Lent shaft, was extended 13 feet. Face in quartz and porphyry. Upraise No. 1 from above drift was extended 11 feet. West crosscut from above south drift was extended 9 feet. West crosscut, 200-foot level, old works, was extended 7 feet. There were employed five miners, one engineer, one blacksmith and carman, one watchman, one foreman.

STANAUARD.—The machinery at the Green creek end of the electric plant was tested this week and everything worked like a charm. The work of retimbering the shaft will be finished in a few days and work will then be resumed in the mine.

Nevada.

VAAY FEW IULA MEN.—Nevada Transcript, May 26: We are informed that there are less idle men in this city than ever known before. Every newcomer that applies for work seems to be successful in getting a job. The appearance of the town seems unusually dull in the daytime, but in the evening the streets are crowded with people. More mining is being done here than for many years past, and consequently there is a greater demand for men.

A RUMOR IN STERKE.—Grass Valley Telegraph, May 27: There was a rumor in town to-day to the effect that some parties who are prospecting on Randolph Flat had been following up a stringer of quartz, and that last night they ran into a "pocket" from which they extracted about \$20,000. We could not trace the rumor to its origin, and do not put much faith in it. Probably the reason that the story started was that some party prospecting on the Byers Taylor ranch below Rough and Ready has struck a rich gold-bearing quartz vein.

BOYNOT THE WORKER.—Grass Valley Union,

May 25: Messrs. Maltman & Burns of Nevada City have purchased the Sulphurets Works on the line of the Narrow Gauge Railroad, erected some time since by Messrs. Higginbottom & Co. The buildings are very large and are directly on the line of the road, which will be a great convenience to the proprietors, as they can handle the sulphurets at a very small cost. It is the intention of Messrs. Maltman & Burns to commence and immediately make all necessary repairs, if there are any to make, and in a very few days they will be ready to commence active operations. Both the gentlemen have had a large experience in the reduction of ores, and there are none better in the State.

HAS RESIGNED.—We learn that W. J. Stewart, who has for so many years been the faithful secretary of the Excelsior Water and Mining Co., has resigned his position. Mr. Stewart will hereafter attend to a drift mine near Rough and Ready, in which he holds a large interest.

A MINING ENTERPRISE.—Grass Valley Telegraph, May 30: Mr. S. B. Fowler of this city, in company with a number of Sacramento gentlemen, has secured a bond on the Granite Hill, better known as the Boston or Wheel mine. A company is being organized and incorporated. Capitalization, 100,000 shares. The Granite Hill gold quartz mine is situated about one mile from the business center of the city of Grass Valley in a southerly direction and on the east bank of Wolf creek, on which are located also many of the great gold-producers of this famous district, notably the Eureka, Idaho, Maryland, Gold Hill, Scadden Flat, Moss Hill, New York Hill, Omaha, Allison Ranch, and is about centrally located relatively to all the present and past large bullion producers. The title to the claim is a United States patent and embraces two thousand linear feet on the lode, extending into the city limits, also 300 feet of the surface on each side of the lode center. Attached to the claim is a water-right, furnishing free power of efficient volume to do all the pumping and hoisting to great depth, also standing timber sufficient to supply all reasonable demands of development for at least five years. Many of the neighboring mines named, together with others more or less remote from the Granite Hill, have yielded hundreds of thousands of dollars in dividends and produced a total bullion output aggregating many millions. The mine has been worked to a depth of about three hundred feet and the shaft has pierced the syenite formation and has entered a slate formation. The ledge has been worked out to a depth of 260 feet; its present size at the bottom of the shaft, according to reports of miners who last worked there, is about 14 inches, being well-defined and heavily mineralized and is in the very best formation. The last 442 tons taken out yielded something over \$19,000, or about \$43 per ton.

Placer.

A BRO STAKE.—Placer Herald, May 27: Hon. Chas. F. Reed made a big strike at his Drummond mine at Forest Hill last week. The ore was taken from what is termed the Eclipse lead and assays from \$20,000 to \$40,000 per ton. As yet the find has not been developed and its extent is not known.

Shasta.

THAY CLAIM A SUCCESS.—Shasta Democrat, May 24: B. Jones and Thos. Harrison, Jr., are making a complete success milling the ore from the Clark mine, formerly known as the old Harrison mine, at Quartz Hill, in Buckeye district. Young Harrison claims to have a secret in preparing quicksilver that makes it a perfect and successful amalgamator. The ore they are milling is refractory, heavily impregnated with sulphur and arsenic. Harrison's prepared quicksilver readily amalgamates the gold. Jones says "the proof of the pudding is chewing the bag." He and young Harrison are making a complete success where all have failed. Their tailings assay practically nothing, their concentrates are not worth shipping, and they are making low-grade refractory gold ore pay a handsome profit. That is proof. The secret of their success is simply in their quicksilver preparation. Having demonstrated the virtue and great value of their process they intend to patent it. Mr. Jones, who has put up the capital to back young Harrison, is more than satisfied. They have been running their mill now two weeks with complete success. We are familiar with the ore in this mine, and have no hesitancy in saying this: If they successfully amalgamate the gold in that ore their secret will work any gold ore in Shasta county, and its value to the mining interests of the county is incalculable. Here is something that the Miners' Association of Shasta County should lose no time in investigating.

BONNAN.—Mr. Coulter, a mining man who has been in the county for several months looking for a mining investment, has located the old Delta mine and the Thompson mine on Dog creek. These mines are about five miles west of Delta. Mr. Coulter was in town yesterday and informed a reporter that he is well satisfied with his prospects on Dog creek. They are developing fine.

BONNAN.—Shasta Courier, May 29: James L. Richardson has bonded or leased the Judge Sweeney mine on Clear creek, near Richardson's, a few miles west of town. A number of men are employed at the Cleveland mine near Middle Creek, which started up recently, making improvements about the mill. Grant Schroter has closed down his mine near the hospital. He has been working four or five men all winter and spring and has taken out some rich rock, but the water is too low to run the pump. We understand that Joseph Bell contemplates taking hold of the property. We understand that operations will be resumed at Bullychoop soon on a big scale. Joseph Bell and Jewett Scranton went out this week to see about starting up their mines there. Quite a force of men were worked at Bullychoop last

season, but the deep snows interfere with winter work. A number of mining men have been in Shasta the past few days looking at property. It is to be hoped that their investigations may result in investment here, and some active work and development. We have plenty of mines and plenty of mine owners here, in fact we are nearly all mine owners, but we lack the dollars to develop our mines. Parties who ought to know about the matter do not confirm the rumor that Iron Mountain is to start up soon. We understand that they intend to make some improvements about the works, but there is nothing definite in regard to starting up the mine and mill. It seems to be the opinion of many that operations will be resumed this year, but the owners have not given out any information on the subject.

SUCCESS AT QUARTZ HILL.—*Redding Free Press*, May 25: We had a talk this week with Bent Jones regarding his success with the ores of Quartz Hill. Bent and young Harrison have five stamps crushing the free-milling ore from the old Clark mine. Heretofore the mine could not be made to pay on account of the arsenic in the ore. Jones says that Harrison has been experimenting for a long time, and as a result of his experiments has discovered a mixture with which he coats the plates and which does away with bad effects of the arsenic. Jones claims that the five stamps are crushing ten tons of rock per day, and that the ore goes from \$10 to \$20 per ton. They have 20 men employed, and the total cost of running the mill and mine is \$50 per day, so it will be seen that there is a good profit realized. Jones will purchase five more stamps shortly, thereby increasing the capacity of the mill at small additional expense.

THE GLADSTONE BOOMING.—Capt. Clark, of the Gladstone Mining Company, was in Redding Thursday. The captain is well pleased with the condition of his mine. He will crush 1700 tons of rock this month and expects to make a good clean-up, as the ore averages well. He contemplates many improvements, such as the erection of a chlorination plant, having now on hand \$25,000 worth of concentrates; also will put in ten more stamps shortly, a new engine, boiler, etc. The miners are drifting east on the vein in the Ohio or lower tunnel, some thousand feet below the apex of the mountain. They are also sinking the Gladstone winze to connect with the east drift from the Ohio. Mr. Clark says that since opening up the Gladstone property he has crushed 45,000 tons of ore. Alexander McCaw, of the Integral Quicksilver Mining Company, was here this week. The works at Cinnabar have started up. Some heavy machinery will be shipped to the mine shortly. Superintendent Thompson of the Mammoth mine, Old Diggings, was here on Monday last. He has commenced a new tunnel, which will be 1800 feet long and will tap the vein about 500 feet deep. Mr. Thompson was in town for timber. L. F. Klemmer showed us a piece of quartz well sprinkled with gold, taken from his mine on the river opposite Rock creek. While running an 80-foot tunnel they put in a small blast on the floor of the tunnel to insert a post, when they discovered that they had run on top of a rich ledge. Robert Elliott, patentee of a "float gold collector," in company with J. D. Simpson, a banker of Paulina, Iowa, and William Vance, owner of the gold beach above Eureka, Humboldt county, arrived here last night, and will try their machine either here or in Trinity county. Mr. Elliott has great confidence in his ability to collect gold from auriferous sands by his process, and he is backed up by several capitalists, among them L. H. Eckhardt of San Francisco, a billiard table manufacturer. Just what this process is we are not advised.

San Bernardino.

MORONOO MINING DISTRICT.—*San Bernardino Times-Index*, May 27: From Knight's hotel to the Rosa mine it is about 20 miles; to Livingston and Allen's mine it is about 27 miles. On the road is Gold Hill and many other mining claims in a greater or less state of development. Gold Hill and a large area of grazing and timber lands are owned by Lucky Baldwin. The mine was worked up to 1878 with a 50-stamp mill. After the mine was shut down the mill was burned, the ruins of which are now standing. Even the tramway used to deliver the ore from the mine to the mill is in a pretty good state of preservation. The houses used by the miners and the officers of the company are standing, being as good as new. Six thousand cords of wood, cut 17 years ago with which to run the mill, remain piled up on the hillsides, somewhat weather-beaten and looking old and wrinkled, but still possessing something of the fire of youth. After having remained idle for 17 years a new company under the direction of Jenks and Lavette has been formed to reopen the mine. A number of men are now at work digging the foundation of a new experimental mill. If it is found that the ore can be worked successfully, then a larger mill will be erected and a big force of men will be kept constantly at work for years to come. Gold Hill, as the name indicates, is a vast ledge of gold-bearing quartz of low-grade ore. The management thinks that it can work three or four-dollar ore successfully. These experiments, if successful, may build up a large mining camp employing hundreds of men. The Rosa mine is now under the superintendency of S. W. Wood—Wheeler, the former superintendent, having made so much money, having worked so hard to bring the mine into a paying condition, that he was compelled to seek relaxation in a trip through the East and to the World's Fair. The mine is now partially developed to the 300-foot level, where a large body of ore 20 feet wide has been opened up, going from \$150 to \$300 per ton. A five-stamp mill goes night and day on the low-grade ores, while the higher-grade ores are shipped to San Francisco by way of Victor. The daily output amounts to from \$200 to \$400

per day, \$60,000 having been taken out this winter. The ore bodies are found in larger quantities at greater depths, and there is enough ore in sight to make the owners independently rich. The orange-growers of Riverside, who own the mine, have proved more successful than some older miners. The mill and hoisting works are of the best. The mill was designed for crushing silver ore, but it works well on gold ore. Only 55 per cent of the gold is saved in working. The dump contains \$50,000 in gold, which some day may be worked over again. The Rosa mine pays out in wages monthly over \$2000. Inglehardt and Cullen of Glendora have the first westerly extension of the Rosa mine, and it has been demonstrated to a mathematical certainty that the easterly end of their claim is at least within 250 feet of the richest body of gold-bearing ore that has ever been opened up in this country. If they do not hit the main ledge at the 300-foot level, there will be something strange developed in mining not before known. Five miles or more beyond the Rosa mine, the Livingstone & Allen mine is located. Experts who have examined this mine say that it is undoubtedly a true fissure vein. It lies in a contact between a slate and limestone formation, just where something rich might be expected. Two shafts have been sunk—one 200 feet deep and the other 50 feet deep. The 200-foot shaft has been partially filled up with debris from a cloudburst, but it will be re-opened at once. In the 50-foot shaft a body of ore that was at first a mere shell has widened out to two feet and runs up into hundreds of dollars per ton.

Sonoma.

COAL.—Arrangements are being made to prospect for coal on a large scale near Mark West, in this county. The Palos Grande Coal and Transportation Company, a corporation composed of Salt Lake and San Francisco capitalists, has bought 2000 acres of land and has raised \$200,000 with which to begin work on the mine and to build a railway from it to the town of Sonoma. From here the company will build a road to Petaluma and thus reach tide-water. The company has let contracts to sink a shaft 500 feet deep, to build a road to Santa Rosa and Petaluma, and to build bunkers, barges and tugs, all to be completed May 10, 1894. Machinery and other material have arrived here, and it is expected the work will begin about the first week in June. Large quantities of good coal have been found in the Mark West neighborhood, and it is thought important mines are sure to be developed.

Trinity.

NEW RIVER.—*Cor. Trinity Journal*, May 27: The mines are looking well and there will no doubt be considerable money taken out this summer. Leas & Nicholson, who have a lease on the Excelsior, have just started the mill. They have 75 or 80 tons of ore out, which is now being packed to the mill. F. J. Ladd has out a run, and will soon start up the Boomer mill. There is quite a lot of ore out from the Sberwood mine ready to be milled as soon as it can be got to the mill. Miller will start his mill in a few days; so you see our boys have not been idle this winter if it has been a hard one. Jas. Mullane came in last week with his train and is packing and hauling the ore.

TAINTY CENTER.—*Cor. Trinity Journal*, May 27: The season has been a very backward one here, as elsewhere, but the majority of all seeds have been planted and are doing fairly well, notwithstanding the fact that there have been several frosty nights. It promises to be a much more favorable season for the miners, who are, after all, the life blood of old Trinity. Prospectors are beginning to arrive with a steady regularity that is decidedly encouraging for the future prospects of this end of the county. A few of the Shasta and Deadwood boys are prospecting in the neighborhood of the Center. Among those from the latter camp are P. McDonald, W. Mortimer, W. Robins and R. McDowell. The boys are having a good time and have been reinforced by G. Simmons and L. Castner from French Gulch, who joined them at their camp on Coffee creek. R. D. Lawrence of Mendocino has returned to his claim on the South Fork; J. M. Cready has returned to his quarters on the same creek; Adams & Magnanant have also taken up their quarters for the season on their mine on Union creek; John Brown has located near the Carr mine; Blackburn & Abrams are working steadily on their claim higher up the creek; S. Conzetta, T. Humpbreys, C. M. Hillyer and J. Bennett are hard at work in Packer's gulch, near Big Flat, and all on Coffee creek. The Parry Bros. are doing well in their claim on the North Fork of Swift creek. L. Baker has also a good claim in that neighborhood. The claims owned by T. Dow, Jr. and Sr., and L. W. Moore on Pool's gulch, and that owned by Dean & Morton, on Hall's gulch, are being worked steadily. There are a number of prospectors on the east side of the river in that locality, among whom are Charley Burns, of Shasta, on Snow gulch; N. R. Brown and J. B. Duncan on Plummer gulch; J. Diddy, S. Cornwell and L. James are working steadily on their mine on Snow gulch. The Bloss & McClary and Haskins mines are working full-banded. The Chinese company are also working steadily. The only quartz mine in the neighborhood is that of J. Strode, near Carrville, on east side of the river. "Jack" is a practical miner and is rapidly getting his mine in working shape. He is putting up a cannon-ball mill and has lots of good-paying ore on the dump ready as soon as the mill is finished. He has got a Huntington mill also, brought up this spring, which he will also set up in due time. This mill, by the way, was hauled over the new road which connects the new bridge with the road to French gulch, but as the county has taken no steps toward finishing the approach on the west end of the bridge, which makes the descent off the bridge a rather

tedious and risky proceeding, as a wagon has to be unloaded and lowered by band and then re-loaded again.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Chronicle*, May 27: 1500 level.—The south west drift, started 75 feet above the sill floor, has been advanced 50 feet in quartz formation of low-grade value. From the end of the southwest drift a west drift has been advanced 15 feet. The first seven feet is in ore of an average assay value of \$25 per ton, and the last eight feet is in quartz formation assaying from \$2 to \$4 per ton. 1650 level.—Have continued making necessary repairs to the drifts on the sill floor of this level and to extract some ore in working west from the old stopes, on the third floor, operating through the apraise, No. 6, carried up from the main northwest drift; also from the old stopes in working north from the crosscut run west from the northwest drift. A south drift started at the end of the crosscut run east from a point 60 feet up in the apraise which was started from the drift run west from these north workings, 27 feet above the sill floor of this level, has been advanced 36 feet; total length, 118 feet; in quartz and porphyry showing some value. Have continued to extract some ore of fair quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. Have extracted during the week from all parts of the mine 223 cars of ore about 225 tons, the average assay value of which per car sample was \$25.65 per ton. The assay value per battery sample of all the ore worked at the Morgan mill during the week (190 tons) was \$23.38 per ton. The Morgan mill has been shut down, and the clean-up of bullion from that mill has been sent to the Mint, the assay value being \$24,154.04.

OPHIR.—1565 level.—The west crosscut started from the bottom of the winze, sunk 52 feet below the sill floor of this level, has been advanced 24 feet; total length, 122 feet; in a porphyry, clay and quartz formation of low assay value. Have continued the work of making the necessary repairs in the shaft, being joint work with the Mexican Company.

MEXICAN.—On the 1565 level.—West crosscut No. 2 from the north drift from the east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 21 feet; total length, 259 feet, continuing in porphyry formation carrying clay separations and fine lines of quartz. Have continued the work of making the necessary repairs in the shaft, being joint work with the Ophir Company.

UTAH.—340 level.—West crosscut No. 3 from the north drift, from west crosscut No. 2, at a point 195 feet in from its mouth, has been extended 15 feet; total length, 181 feet; continuing in quartzite for 12 feet, the last three feet is in porphyry formation.

SIERRA NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 13 feet, making the total length 360 feet; the face is in porphyry and streaks of quartz. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 18 feet, making the total distance west of the joint shaft 3210 feet; the face is in hard porphyry.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level, has been advanced the past week 18 feet, making the total distance west of the shaft 3210 feet; the face is in hard porphyry.

ANNES.—On 420 level, have cleaned out east crosscut No. 3, and put in car track to north lateral drift. In north lateral drift put in car track to east crosscut No. 5. Will use this lateral drift instead of the main north drift.

GOULD & CURRY.—200 level.—West crosscut No. 5, started in northwest drift, 432 feet from main west drift, has been advanced 8 feet; total length, 483 feet; face in hard porphyry. Also did some repairing on the 300 and 400 levels during the past week. Suro tunnel level.—At a point in east crosscut No. 1, 75 feet from the main north drift, we have started jointly with the Best & Belcher Company north on a streak of quartz and extended same 10 feet; face in porphyry and quartz. Also did considerable repairing work during the week.

BAST & BELCHER.—200 level.—During the past week west crosscut No. 2, started in northwest drift, 230 feet from our south line, has been extended 16 feet; total length, 116 feet; face in quartz and porphyry. 300 level.—West crosscut No. 4, started in southwest drift 112 feet from west crosscut No. 3, has been extended 12 feet; total length, 82 feet; face in hard porphyry and quartz. Suro tunnel level.—At a point in east crosscut No. 1, 75 feet from main north drift, we have started jointly with the Gould & Curry Company north on a streak of quartz and extended same 10 feet; face in porphyry and quartz. Also did considerable repairing during the past week.

HALE & NOACROSS.—1800 level.—Advanced the apraise in west crosscut on our south boundary 14 feet; total height, 50 feet; the top of apraise continues in quartz yielding low assays. Main shaft.—Are retimbering above the 1300 level and continue making the necessary repairs in main incline.

CHOLLAR.—The repairs to the north drift, 850 level, are not yet completed. The east crosscut near the south line, 930 level, is out 246 feet; face in the porphyry.

POTOSI.—The north drift from east crosscut, 850 level, has not been advanced any on account of timbering. The south raise 80 feet south of Potosi winze, 930 level, is up 94 feet; formation in top is porphyry. The north drift from east crosscut, opposite the Potosi winze, 930 level, is out 94 feet; face is in five feet of

fair-grade ore. The north raise, 1000 level, is up 109 feet on the slope; top shows six feet of fair-grade ore. South raise, 1000 level, 20 feet south of top of raise from 1100 level, is yielding fair-grade ore. The west crosscut, 1000 level, 120 feet south of top of raise from the 1100 level, is out 37 feet; face is in porphyry. Extracted and sent to Nevada mill the past week 545 tons and 250 pounds of ore from the 550, 930, 1000 and 1150 levels. Milled during the week 525 tons. On hand at mill 120 tons and 1250 pounds. Average battery assays, \$25; average car sample assays, \$25.44. Shipped to the U. S. Mint, Carson, 418 pounds crude bullion.

OCCIDENTAL.—Crosscut No. 6 from north drift, 750 level, is in 43 feet; face is in quartz and porphyry. No. 7 crosscut from the same drift is in 20 feet and is showing seams of pay ore. The main south drift on 650 level has been extended 8 feet; total distance from No. 1 winze 310 feet; the face of the drift is in ore assaying \$18 per ton. The Zadir drift, Suro tunnel level, has been extended 25 feet; total length, 1008 feet from the main tunnel, and is in quartz and porphyry.

KENTUCK.—We continue to extract from two to three tons of ore per day from the 160 level of the average value of \$30 per ton. On the 1100 level we are extending the south drift and have started a raise above the track floor near the north line. The raise is up 15 feet and is in fair-grade ore. The joint west crosscut near the Jacket south line is in 64 feet; face is in clay and porphyry.

WAAN SHAFT.—Are yet repairing the shaft at different points below the 1600 level, and replacing the pipes.

ALPHA.—Are yet engaged in repairing the Ward shaft at different points below the 1600 level, and replacing the pipes.

BULLION.—The repairs to the Ward shaft and replacing pipes below the 1600 level are not yet completed.

EXOREQUER.—Are yet engaged in repairing the Ward shaft at different points below the 1600 level, and replacing the pipes.

CON. NEW YORK.—The south drift from the bottom of the winze below the 650 level is in a distance of 60 feet; the face is in quartz, some of which gives fair assays. The west crosscut from southwest drift, 800 level, is in a distance of 36 feet; formation hard porphyry.

SILVER HILL.—The southeast drift on the 450 level has been advanced 5 feet during the past week, making the total distance from north line 123 feet; the face is in hard porphyry.

Taylor District.

STARTER UP.—*Pioche Record*, May 27: The Monitor mill at Taylor started up last Monday. Teams have been engaged hauling ore for some time. This is good news for that section.

Pioche District.

OLD TIMES.—*Pioche Record*, May 27: The shipment of ore recently made from the Old-Timer brought \$104 a ton. The shipment was made in order to find out the value of the ore, as the assays widely varied. The returns from Salt Lake show that it went 87 ounces silver, half an ounce in gold and 64 per cent lead to the ton. The owners, Messrs. Schofield, Spillman and Flynn, are well satisfied with the result.

FROM BULLIONVILLE.—Large supplies of salt and lumber are constantly arriving. The new tanks are all in place and will soon be ready for operation. The gates are in and the sluiceways nearly finished. Leaching through them will probably be begun early in the June days. Manager W. S. Godbe leaves for Salt Lake next Sunday to be absent about ten days. The stockholders' meeting of the Pioche Con. Co. at Salt Lake on the 5th prox. is one matter which requires his attention. The Howell roaster was fired up Tuesday preparatory to what is expected to be a long and profitable run. It will not now be necessary to stop the furnace for want of cooling floor space, as an abundance of this is provided.

Silver King District.

TO COMMENCE WORK.—*Enreka Sentinel*, May 27: C. J. Boskowitz and John J. Cupid of White Pine county, came in Tuesday evening by way of Silver King district. Bosko is one of his quarterly trips and complaints of dull business generally. These gentlemen are interested in some of the best mines in Silver King district, and think of commencing work there on something of a large scale. They have three claims which are regarded as particularly good prospects. When the Wheatley Bros. get their furnace in running order there Cupid expects to dispose of a considerable quantity of low-grade lead ore, which is already mined there, but too low to ship to Salt Lake.

White Pine District.

ACTIVE.—*White Pine News*, May 20: There is great activity in local mining operations in this district just at present. A new discovery made by Newt Boyd and Thomas Rockhill has given a new impetus to the mining interest. The new find is named the "Hell of the Hell," and shows a vein of five or six feet, carrying \$30 gold ore. There was a rush for the adjoining ground and it was quickly gobbled up. One of the claims has already been bonded to D. H. Jackson, the mining man who has been here for some time examining the Chairman property, and he has put four men to work on it.

UTAH.

A \$600,000 BOND.—*Salt Lake Journal*, May 27: The directors of the Deseret Company held an important meeting yesterday, at which important arrangements were made for a test run on their ore by the Bully Boy & Webster mill. If the results are satisfactory they will either have that company work their ore or

lease the mill for five or six months, at the end of which time the company expect to have a large mill of their own built and ready for business. The company also acted favorably upon the application of English people for a bond on the property for a period of nine months in the sum of \$600,000 net to the company. The latter, however, will continue to operate the property, and should the developments be such that they desire to recede from the bond they can do so by the payment of a specified bonus.

THE PETRO DRAINED.—For two years past the Petro Company, at Bingham, have been running a tunnel to tap and drain the shaft, which has a depth of 600 feet. The tunnel was run from the opposite side of the hill and is 1000 feet long. S. B. Milner informs the *Journal* that the connection was made yesterday, and that 350 feet of water, which was in the shaft, was booming out, carrying with it the track and two or three cars which were in side drifts. All that has yet been discovered of the latter are two or three wheels, while the T-rails are twisted all out of shape and rendered entirely useless. The surveys for this great work were made by Robert Gorlinski, and so accurate were they that the tunnel hit the shaft plumb center, which is especially worthy of mention as he was compelled to work over a hill. The draining of the workings puts the mine in the best possible condition, and Mr. Milner informs us that the mine will be a heavy shipper in the future.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING MAY 23, 1893.
498,150.—STUMP EXTRACTOR—J. Abhee, Reno, Nev.
497,942.—RETURN SIGNAL KEY—J. M. Bell, Tacoma, Wash.
497,911.—TREATING COCAINUT HUSK—J. T. Davis, S. F.
498,109.—PUMP GEARING—S. L. Fulford, Los Angeles, Cal.
498,210.—METAL PIPE LOCK JOINT—C. S. Hamilton, Los Angeles, Cal.
498,135.—CONDUIT ELECTRIC RAILWAY—G. F. Moffett, Portland, Or.
498,075.—CAPSTAN—W. F. Murray, S. F.
498,215.—BOMFAR FOR CABLE CROSSINGS—H. E. Peshman, S. F.
497,821.—PIPE EXPANDER—S. D. Robertson, Undine, Cal.
497,820.—LUBRICATOR—L. J. Rogers, Santa Rosa, Cal.
498,084.—PLUMS LEVEL—L. J. Rogers, Pomona, Cal.
497,822.—ELECTRO THERAPEUTICAL APPLIANCE—H. C. Royer, Los Angeles, Cal.
498,085.—VACUUM PAN—C. L. Schallitz, S. F.
498,083.—CALENDAR AND STAMP HOLDER—C. C. Stallman, S. F.
498,090.—STUMP-PULLER—T. A. Terrell, New Whatcom, Wash.
498,043.—FIREARM—C. M. Wollam, S. F.
497,853.—FRUIT-TREE SCISSOR—J. Wright, Los Angeles, Cal.
22,451.—DESIGN FOR CANE—W. S. O'Brien, S. E.
NOTE.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail for telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast Inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

COMBINED ROTARY CALENDAR AND STAMP-HOLDER.—Chas. C. Stallman, S. F. No. 498,088. Dated May 23, 1893. The object of this invention is to provide a convenient calendar, showing the days of the week, and, in conjunction therewith, a mechanism for displaying the successive weeks and months of the year, removing those which have already passed, and forming a stamp-holder and handle upon the calendar, whereby the whole is arranged in a convenient single article of desk furniture.

CAPSTAN.—Wm. F. Murray, S. F., assignor of one-half to Samuel Murray. No. 498,075. Dated May 23, 1893. The invention relates to a capstan or apparatus for winding ropes for the purpose of hauling logs or other articles, or for doing work upon vessels. It consists of a winding drum, in connection with gearing, whereby the speed and power of the drum may be changed to suit the character of the work being done.

VACUUM PAN.—Carl L. Schallitz, S. F. No. 498,085. Dated May 23, 1893. This invention relates to an apparatus for evaporating in vacuo, and for continuously supplying and discharging the material so that the apparatus can be run continuously instead of by separate charges, and to partly evaporate the material with vapor from the material which is being evaporated. It consists in certain details of construction.

Market Reports.

The Markets.

SAN FRANCISCO, June 1, 1893.

In the review of the iron situation the *American Manufacturer* says: "So far as market conditions are concerned there is very little change, though in some quarters there are evidences of a stronger undertone. The extreme depression seems to be over. The advance in southern freight rates has not been followed as yet by a very marked demand in Pennsylvania, for whose advantage the advances were made. This action will have less effect on southern pig iron shipments than might be supposed. Large buyers in all markets continue to buy sparingly, although it was rumored in Chicago that possibly some very large transactions in southern iron might soon be recorded. The probabilities seem to favor large business in steel billets at an early day. Both buyers and sellers are tired of the past hand-to-mouth policy and negotiations were opened a few days ago at both eastern and western manufacturing centers, which indicate large sales soon. The merchant iron mills are not accumulating many orders, though all are running full time. Sheet mills are doing well, and nail factories, hardly with an exception, are enjoying a large, though not remunerative trade. In other branches the signs are for more business, but the fundamental conditions have not been modified. Railroad requirements will soon assume a more satisfactory shape, though they will not be sufficient at any time this year in greatly influence the market. Building and agricultural requirements are quite large. Foundry and machine shop works reported abundant at all points. Small equipments for shops are in good demand."

THE METALS.—Tin has shown a steady decline during the week. Copper and lead are dull.

Mining Share Market.

There has been very little doing in mining stocks outside of a movement in Potasi. On Wednesday, during the forenoon, Potasi, which closed on Monday at \$2.85, sold as high as \$3.35. Then came some lively fluctuations, on a descending scale, and Potasi went back to \$3.05. Most of these erratic gyrations in the stock were caused by the manipulations of a little clique who are heavily short on the stock and are trying to make deliveries of shares from day to day and at the same time keep their line of shorts out. Whenever the stock is strong they buy in the "regular way," at a loss, enough stock for delivery and then ask the sellers to make the stock "cash," so they can get it for delivery, and then they turn in, sell out an equal number of shares "regular," so as to keep up their short end. For many days past there has been a difference of from 10 to 30 cents per share between their purchases and sales and always against them, so the clique have been losing heavily in their efforts to wreck Potasi.

In this connection, the *Post* says: "It is about time to enter another protest against the way in which news from the Comstock is manufactured on Pine street and then revamped in the local papers as if obtained direct from the mining officials on the lode. There should be some more reliable means for furnishing speculators with information, especially when a development takes place like that in Potasi. Second-hand news of the kind is thoroughly unreliable and misleading."
"W. E. Sharon, superintendent of Yellow Jacket and other south-end Comstock mines, is in town. Mr. Sharon says there is no foundation in the greater portion of the stories told about dull times on the Comstock." While affairs are not as lively there as they ought to be, the prospects at several points along the lode are very cheering, and it is only a matter of time until a general revival may be expected. So far as the Jacket development is concerned, some good ore has been found in hunches, and it is hoped that these may yet lead to something of importance. Of the Potasi mine Mr. Sharon speaks in the most favorable terms."

WHO PAY TOLL?

USE THE CELEBRATED
BRYAN ROLLER QUARTZ MILLS.

HOW?

BECAUSE it is the simplest Roller Mill made, therefore IT SAVES IN RUNNING EXPENSES.
BECAUSE it is the only Roller Mill made in which oil is prevented from dropping into the pulp (oil makes it impossible for the quicksilver to amalgamate with the gold), therefore IT SAVES THE GOLD FROM GOING INTO THE TAILINGS. Isn't this tollage?
BECAUSE—well, there are too many ways of paying toll, and besides it would only weary you to read of them.
All who use the mill can testify to its merits. We want to sell you a mill, so write to us for testimonials and particulars, or to some of the users—it makes no difference.

A FEW OF THE USERS:

THE CANDELARIA CONSOLIDATED MINING CO., San Dimas, Dnrago, Mexico.....	4 mills.

SAN FRANCISCO, Cal.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vexation and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also leave very fine sculptures and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

Miners Looking for Work.

Our correspondent, Mr. Schaeffe, calls attention to the great number of idle miners in the camps in the interior of this State. Most of these men have come from silver districts in other States where there is little or no work for them, hoping to find employment in the gold mining regions of California. They know that the gold mines are kept going, and suppose this State the best place to come to for work. But there are already plenty of miners here, there being in fact a surplus. Since the closing of the hydraulic mines some years ago, many employed in that industry had to go into the quartz camps, and there was not employment to be found for one-quarter of them. Numbers have gone into other avocations but always stand ready to come back into mining when opportunity offers.

In what are known as the mining counties of the State there is a large element of the population which has always followed mining for a living and knows no other business. These men dislike the humdrum life of a valley rancher and will not leave their mountain homes unless compelled to by stern necessity. They have become strongly attached to the mountain region where they have passed most of their lives, have built their homes, and raised their families; and it is like a strong tug at their heart-strings when they have to leave. But many of them have been compelled, during the past ten years, to move away from the little mountain camps, because the gravel mines have been closed down, and the towns have gone to decay. The business left the men; not the men the business. Still, those who have had to come to the valleys to earn a living for themselves and families, turn with longing eyes towards the mountains and avail themselves of the first opportunity to get back. When there is a flutter of excitement in any of the old places, as for instance at present in Forbestown, Butte county, Angels, Calaveras county, or Vanderbilt, San Bernardino county, these men, always on the lookout, are the first to go, and before the news goes outside the State, there are plenty of California miners on hand for work.

It is useless for men from Nevada, Montana, Idaho or other places to come here in expectation of finding work. There are more than enough miners here now, and good skillful ones too. There is no expectation of any hydraulic mines starting up this year and the quartz mining districts

are full-handed. If men have a stake, and want to prospect that is a different thing, but looking for mining work for wages will be disappointing.

Freight Rates on the Bay.

Speeches, pamphlets, editorials, letters, talk or resolutions, popular opinion, proceedings of conventions, chambers of commerce, boards of trade, etc., appear to have little or no effect on the Southern Pacific Co. toward inducing it to cut down freight rates; but a very little practical opposition appeals to the company at once in a

Of course the ferry service of the railroad company is much more complete than that of the opposition line, but the latter has accomplished a great object. One of the big concessions of the new tariff is the provisions that wagons returning empty after delivering a load of freight shall not be charged anything. Heretofore in returning the empty the charge has been \$1.25 for wagons drawn by four horses, 75 cents for a wagon and two horses, 65 cents for a truck drawn by one horse, \$1 for a truck and two horses and \$1.50 for a truck and four horses.

The concession that freight on wagons shall only be charged 50 cents a ton means a reduction in many cases of

50 per cent and 75 per cent in other cases, because the old ferry tariff of April 5, 1893, provided that "for all goods, merchandise or freight conveyed upon the steamer in wagons or trucks with horses attached the charge will be at the rate of 5 cents per 100 pounds * * * Loaded wagons without teams will be charged at the rate of 7½ cents per 100 pounds."

The ferry tariff of the company includes some 270 kinds of merchandise. Under the tariff just superseded rates were divided into two classes, viz, a rate per 100 pounds for any quantity less than a ton and a rate per 100

100-TON HIGH-SPEED ELECTRIC TRAVELING CRANE AT THE BALDWIN LOCOMOTIVE WORKS.—See page 355.

way which makes it respond. It is not a little strange that practical opposition has appeared for the first time in the upper part of the State at Oakland, a city which has the reputation of being in the hands of the railroad company. Not long since the completion of an electric railroad from Oakland through Fruitvale to Haywards, caused the company to make concessions in passenger rates; and now an opposition ferry between this city and Oakland makes the company order a big cut in the freight tariff. The new bay opposition is carried on in a small way, too, yet it has had an almost immediate effect. The Whitney Transfer Co., carrying on an express and freight business, has been paying the Southern Pacific about \$20,000 a year for freight, and the management determined to reduce expenses. A small steamer was fitted up, wharf leases made, and the steamer commenced running, carrying the Whitney and other wagons and freight at a reduced rate. Passenger fare was put down to 5 cents, while the Southern Pacific charges 15 cents. The Southern Pacific Co. therefore reduced freight rates on this route from 50 to 75 per cent. The passenger rates are unchanged because the new ferry line has very limited accommodation for anything but freight.

pounds for lots of one ton or more. The rates in quantities of less than a ton remain unchanged. It is the rate for a ton of freight and over that has been reduced down to a sweeping rate of 50 cents per ton on the deck of the vessels. Some of the merchandise that formerly took a rate of \$1 will now take 50 cents for a ton or over, includes baking powder, wines, liquors, ale, porter, beer, barley, bread, crackers, borax, catsup, cake, coffee, crockery, fish, feathers, dried fruit, hardware, mustard, paints, paper, pepper, raisins, rice and rope. The articles that have had their rate reduced from \$1.50 to 50 cents a ton and over, include clothing in boxes and bales, drygoods in boxes or bales, green fruit, vegetables, furniture, plate glass and window glass. The great majority of the commodities included in the ferry tariff will by the reduced tariff take a rate of 50 per cent lower, because most of the articles heretofore have been charged 5 cents per 100 pounds when shipped in quantities of a ton or more. The company's rates per 100 pounds on shipments of less than a ton range from 2½ cents to \$4. The great majority of these rates are, however, 20 cents and lower. The opposition steamer is being well patronized in freight shipments.

Comment.

As will be noticed from the Nevada news in our Mining Summary on another page more attention is being paid than formerly to the gold camps of that State. While Nevada is generally known as the Silver State it has always produced more or less gold. The principal mines on the Comstock yield a much larger percentage of gold than do the ores of ordinary silver districts of the country. But there are many smaller camps in Nevada where gold ore is produced, to which attention is now being turned. In most of these the ore is of a rather low grade and ten years or so since could not be worked at a profit. Now, however, with silver mining unprofitable, and improved and more economical methods in working gold ores, these camps are being prospected and developed. With very few exceptions silver mines are not paying, and as there are many people in Nevada who know no other business except mining it is natural that they should begin to look up the gold mines and see what can be done with them.

The Golden Reward Mining Company of the Black Hills, Dakota, shipped a lot of ore for experimental treatment to the Chick Quick process plant at Pittsburg, Kan., but the process people refused permission to the mining company's president to come and see the process operated, and that ended the business, as it should have done. A "process man" who has a metallurgical secret should be allowed to keep it and the miner should put no faith in him whatever. The patent laws of this country are good enough to protect an inventor, and if he really has anything of value he can afford to patent it, let the people know what he has and charge them for using it. No man can tell what tricks are being played upon him if a process is only worked in secret by the inventor himself. It may be that the Chick people have a valuable method of treating ores, but confidence is not inspired in it by a refusal to let people interested see the operation. This is the same Chick process which was tried in Shasta county, in this State, but it is not being worked there at present, as far as we know.

The Sacramento *Record-Union* quotes the *Call* of this city as saying that "San Francisco's opinion of hydraulic mining is that it would be better for the State if there was not the color of gold on the Sierra Nevada Range." Could anything be more absurd than such a statement as this! This city was built with the gold of the Sierra Nevada Range and prospered until the supply was partly cut off. For two-thirds of the time since this State was organized it was absolutely dependent for its existence on the gold in the Sierra Nevada Range and mining was the principal industry of its inhabitants. As to the city, since the decadence of mining and the supremacy of agriculture it has never been prosperous. The *Call* is altogether mistaken in thus expressing San Francisco's opinion. The senti-

ment is the other way. Not many months have passed since the San Francisco Board of Supervisors, the Chamber of Commerce, the Board of Trade and other bodies which represent the opinion of San Francisco, passed strong resolutions asking Congress to do something to rehabilitate the hydraulic mining industry of California. The State Legislature did the same thing. Of the \$20,000 collected to aid the mining industry, to which all counties contributed, San Francisco gave about 75 per cent, and most of this was donated by merchants, business men and manufacturers. Such things as these do not denote the existence here of any such opinion as the *Call* supposes. In fact they prove exactly to the contrary. The *Call* is writing of a period of ten years ago when it refers to hydraulic mining, but opinions have changed materially since then.

Most of the silver mining camps of the country are in a depressed condition, but Park City, Utah, appears to be an exception to the rule. The *Record* states that in spite of the low price of silver and lead a very active season is expected at Park City. Men are being put on almost every day and an immense quantity of ore is being sent to market. The indications are that the Ontario company will build the new leaching plant now under contemplation, while there is a fair chance for one or two new shippers being added to the present list. Looked at from almost any standpoint, the outlook is promising, to say the least, and the business men are beginning to feel the stimulus of promised larger pay rolls. It is refreshing to find at least one silver camp with a prosperous outlook.

Forbestown is in the southeastern part of Butte county, near the boundary line of Yuba and Nevada counties, and is about one and a half miles from the south fork of the Feather river. It is not a new town nor are its mines new ones, but it has just come to the front with a mining excitement. The quartz mines have been known for a long time but under the conditions existing when they were originally discovered they did not pay. These conditions have gradually changed until a few enterprising men found that there was money in the ledges and started in to develop them properly. Others followed and other mines were opened so that now the region is becoming noted as a quartz camp of prominence and the best prospects. There are other places in the State which will have a similar history in due time as new men come in who recognize better than the older inhabitants the advantages possessed. The low grade propositions formerly ignored by miners will all come to be worked some day, for ledges of gold ore are in demand and modern scientific methods enable men to make a profit out of ore that formerly "went over the dump."

The California Debris Commission Organized.

It is with pleasure we note the organization this week of the California Debris Commission, under the provisions of the so-called Caminetti Act, approved March 1st. About a month since, the President appointed on this commission the following officers of the Engineer Corps, U. S. A.: Col. W. H. Mendell, Lieut. Col. W. H. H. Benysaard and Major W. H. Heuer. There was at first some little doubt, caused by the manner of their appointment, as to whether these gentlemen could serve on this commission, for which duty, by the way, they receive no extra compensation. They held a preliminary meeting and decided to submit certain questions to the U. S. Attorney-General before completing their organization. They are all members of the U. S. Army, and, it seems, are not permitted by law to accept civil appointments while holding their army positions. Their commissions as Debris Commissioners are signed by the President of the United States and apparently in the form of entirely new appointments.

Col. Mendell wrote to the Secretary of War and he submitted the matter to the Attorney-General of the United States. On Wednesday of this week an answer was received, and the opinion of the Attorney-General was given that the appointments were in the nature of an order from the Secretary of War, and not mere civil commissions. Accordingly there was nothing to do but to accept the positions, and on Thursday the Commission was organized by the election of Col. W. H. Mendell as president and Major W. H. Heuer secretary and disbursing officer.

The Commission is therefore ready for business and has formulated the following rules by which proceedings before it will be conducted:

SAN FRANCISCO, June 8th, 1893.

The California Debris Commission, appointed under the Act of Congress approved March 1, 1893, publishes for the information of all concerned sections 9, 10, 11 and 12 of the law which governs in the matter of presentation of petition and proceedings therefor:

SEC. 9. That the individual proprietor or proprietors, or in case of a corporation its manager or agent appointed for that purpose, owning mining ground in the territory in the State of California mentioned in section three hereof, which it is desired

to work by the hydraulic process, must file with said commission a verified petition, setting forth such facts as will comply with law and rules prescribed by said commission.

SEC. 10. That said petition shall be accompanied by an instrument duly executed and acknowledged, as required by the law of the said State, whereby the owner or owners of such mine or mines surrender to the United States the right and privilege to regulate by law, as provided in this act, or any law that may hereafter be enacted, or by such rules and regulations as may be prescribed by virtue thereof, the manner and method in which the debris resulting from the working of said mine or mines shall be restrained, and what amount shall be produced therefrom; it being understood that the surrender aforesaid shall not be construed as in any way affecting the right of such owner or owners to operate said mine or mines by any other process or method now in use in said State: *Provided*, That they shall not interfere with the navigability of the aforesaid rivers.

SEC. 11. That the owners of several mining claims situated so as to require a common dumping ground or dam or other restraining works for the debris issuing therefrom in one or more sites may file a joint petition setting forth such facts in addition to the requirements of section nine hereof; and where the owner of a hydraulic mine or owners of several such mines have and use common dumping sites for impounding debris or as settling reservoirs, which sites are located below the mine of an applicant not entitled to use same, such fact shall also be stated in said petition. Thereupon the same proceeding shall be had as provided for herein.

SEC. 12. A notice specifying briefly the contents of said petition and fixing a time previous to which all proofs are to be submitted shall be published by said commission in some newspaper or newspapers of general circulation in the communities interested in the matter set forth therein. If published in a daily paper, each publication shall continue for at least ten days; if in a weekly paper, in at least three issues of the same. Pending publication thereof said commission, or a committee thereof, shall examine the mine and premises described in each petition. On or before the time so fixed all parties interested, either as petitioner or contestants, whether miners or agriculturists, may file affidavits, plans and maps in support of their respective claims. Further hearings, upon notice to all parties of record, may be granted by the commission when necessary.

The petition must, in addition to fulfillment of the requirements of the law, contain, or be accompanied by, a full description covering the following points and by such maps as may be required for illustration of the question:

The name, location and extent of the mining ground; the route of travel thereto; the river which the drainage of the mine reaches and the names of the tributaries which it follows; the height of the bank to be mined; the character of the gravel; the source of the water supply; the length, fall and dimensions of the ditch; the length of the mining season; the number of inches of water proposed to be used and under what pressure; the daily duration of mining proposed, whether for 24 or fewer hours; the fall of the sluice in 12 feet; dimensions of sluice and the amount of gravel to be handled in an hour; the character of restraining barriers existing or proposed; a description of the site for impounding debris; its area and capacity; position and character proposed for the barrier.

Brevity and clearness are to be studied in these descriptions.

The above-stated information may be sufficient to enable the commission, in some cases, to dispense with maps, but in all cases of importance maps of the mining ground and of the reservoir sites will probably be necessary, and in all cases will probably expedite the action of the commission. The commission prefers, for expedition, but does not at present insist, that each case should be presented by a mining or civil engineer capable of giving necessary information.

It will expedite matters if all the miners in one particular locality will prepare and present their petitions as near as possible at the same time, in order that the mines may all be examined during one visit of the Commission.

In cases of a joint petition contemplated in Section 11, there should be a separate statement from each individual mine as to its proposed output, amount of water, etc., the same as provided for a single petition.

All maps, plans, petitions or writings of any description on file in the office shall be open for examination by any interested party.

On the seventh day following the date fixed in the advertisement, the Commission or a committee thereof will attend in its office to meet the petitioners and contestants, for the purpose of gaining by inquiry such explanation as may be necessary for a full understanding of the case.

The Commission or committee may, in its discretion, cause to be read any papers, and may examine maps, plans or drawings on their files.

The commission does not invite oral addresses and prefers that all questions submitted for its consideration be presented in writing.

The commission may receive on this occasion any additional papers presented to it if they are deemed useful in further consideration, or may admit additional papers filed before a specified date.

The office of the commission is for the present established in room 89, Flood Building, San Francisco.

All communications should be addressed to Major W. H. Heuer, Corps of Engineers, room 89, Flood Building.

It will be noted that the Commission organized very promptly after being assured of their position. It is a matter of common report, however, that none of the members desired an appointment on the Commission, as they already have sufficient duties to attend to without these new ones being added. This is rather unfortunate, since it will lead to delay in the consideration of applications for license to mine, and it will take longer for miners to get started to work than they now suppose. This subject is considered in another article in this number of the PRESS.

A THIRTY-TON GASOLINE SCHOONER is being built on Dickie's ways at Old Sausalito for Campbell Brothers of Bodega. She is guaranteed to make eight knots an hour

The Resumption of Hydraulic Mining.

The machinery of the law is now ready to consider the resumption of hydraulic mining in California. Congress and the State have passed the necessary laws; the California Debris Commission has been appointed; the Commission has organized; established headquarters, elected its officers and formulated its rules of procedure. The hydraulic miners may now make their applications for licenses to mine.

But the miners are going to be disappointed in one thing—they will not be able to resume work as soon as they have supposed. It is going to take longer to arrange the preliminaries than was imagined, and those who want to prepare for next season must at once get ready to apply for their licenses.

The new California Debris Commission has been considering this question of the time necessary to complete, under the requirements of the law, an inquiry brought by the presentation of a petition to mine. They figure it up in about this way: Preliminary consideration of the petition, about 7 days; application to the Secretary of War to advertise the abstract of petition, 15 days (this is a requisite of the regulations of the War Department); time for advertising, 21 days; visit to mine pending publication, hearing and deliberation, 30 days; examination of plans and specifications, about 20 days; second examination of mine, 10 days; third examination of mine after works are constructed and before final license is issued, 10 days; this makes 113 days without counting the time necessary for the construction of the impounding or restraining works, which, however, may be going on meantime.

This shows that it will take about four months from the time of the presentation of the petition to the issuance of the license under ordinary circumstances, and if there are contests, or difficulties arise, it may take more. Then again all the commissioners have other duties to perform and cannot give their entire time to the mining question. The War Department naturally considers the river and harbor improvement of the Pacific Coast of more importance than one branch of the mining industry, and this work is in charge of the gentlemen comprising this commission. They have also charge of the fortification and lighthouse engineering and various other matters, all of which now take up most of their time.

They cannot permit the mining debris question to occupy all their time to the exclusion of their other duties, and are often absent from the city engaged upon these duties. The harbors of the entire Pacific Coast of the United States are within their jurisdiction.

They will try to simplify matters as far as possible, as their rules of procedure, published in another column, show. They evidently intend to prevent general discussions and the delivery of long speeches, for they want facts presented in writing. And they seem also, to be in search of engineering rather than legal facts, which is in line with the statements of the MINING AND SCIENTIFIC PRESS that the question had passed from the domain of law into that of engineering.

Now that the hydraulic miners of the State have an idea of the time required to obtain a license to mine, it will be to their interest to at once make the necessary preparations, and not delay until within a few weeks of the mining season. If they do so delay, the fault will be with themselves, not the Debris Commission.

Mine Bell Signals.

We enclose with this number of the MINING AND SCIENTIFIC PRESS to all subscribers in the mining districts a copy of the mine bell signals and rules required by the Vorhees Act, passed by the State Legislature. We have already published this law in full. The copy we send out to the miners is the full legal size, of three feet by one, such as is required to be posted on each level of a mine, and in the engine room of the hoisting works. Other copies printed on cloth to withstand dampness may be obtained at this office for fifty cents. It should be remembered that every mine in this State must post these signals at the various points required by the Act, and they must be signed by the superintendent or owner of the property.

The system adopted is not quite so simple as could have been wished, and many superintendents complain of their intricacy. But the law must be complied with or the penalties may be enforced.

In the full-size copy which we print, space has been left to indicate the station or level signals. We have put no numbers in this space, because each superintendent may arrange that to suit himself and mark the signals with a pen or stencils. What we have printed is only what is required by the law. Any subscriber who wishes one of these copies may obtain it free, printed on paper, by application at this office; but for the copies on cloth a charge is made.

The Electric Traveling Crane.

In an address before the Franklin Institute last March, on the subject of the "The Modern Traveling Crane," Mr. Alexander Onderbridge, Jr., describes a mammoth traveling crane in use at the new erecting shop of the Baldwin Locomotive Works. It is of 100 tons capacity, has electricity for its motive power and was made by Wm. Sellers & Co., of Philadelphia. The engraving on the first pages shows the application of this crane. The span of the bridge is 74 feet 8 inches; length of runway, 355 feet; speed (under absolute control) as follows: bridge travel, 100 and 200 feet per minute; trolley travel, crosswise, 50 and 100 feet per minute; hoisting and lowering, 5, 10, 20 and 40 feet per minute.

The elevated railway traveling crane consists of four essential parts: the elevated tracks; the traveling bridge; the trolley car traversing the bridge and carrying the hoisting mechanism; and the motor or driving mechanism.

The bridge is constructed of two parallel plate girders extending from rail to rail of the elevated tracks, spanning in mid-air the breadth of the building, and on the ends of these are the double-flanged steel-tired wheels. Between the girders heavy steel tracks are laid, upon which a trolley car carrying the hoisting mechanism runs back and forth. By the method of construction of the girders forming the sides of the bridge great rigidity is secured, while the entire space within and beneath the bridge is left unobstructed for the working of the trolley car and machinery. The car which travels on the bridge tracks is provided with a grooved drum and depending double chains wound therein, carrying a forged swivel hook mounted securely in a hoisting block on ball-

bearings, the block being furnished with sheaves through which the chain runs. The friction on the swivel is so reduced by the ball-bearings that it was found in actual trial that a load of 50 tons suspended from the hook could easily be rotated by one man. The winding of the double chain in the grooves of the drum is always toward the center; this insures a perfectly vertical lift of the load, an advantage always and a necessary feature in many instances. This is shown in the small cut.

In the Baldwin shops, the 100-ton electric giant picks up a completed "Mogul" or "Decapod" engine of the largest size, carrying it swiftly over the heads of the workmen and depositing it gently on a railway siding near the exit. Retaining clutches automatically hold the load securely from the moment it leaves the floor until it is re-deposited. The chain can never run down, but the load must always be pushed down by the operator moving a lever.

The operator's post is on a platform or cage supported at a convenient point under the bridge; by simple lever movements he applies the motive-power to drive the bridge along the rails and simultaneously to drive the trolley across the bridge, so that, during the two motions at right angles, the hook depending from the chain travels in the resultant diagonal direction until it is vertically over the object to be hoisted. A simple application of power revolves the drum, lowering the chain, and when the object is attached, a like delicate touch of the lever in the opposite direction causes the drum to revolve in the opposite direction, winding up the chain and lifting the object to the desired height. The bridge and the trolley are again started in their respective longitudinal and cross movements, the suspended object traveling in a straight line—the resultant of the two directions—from its starting point toward its destination, until vertically over the exact spot where it is to be deposited, when it is a simple matter to lower and adjust it in place. The speed of all of these movements is under absolute control of the operator, and the precision of adjustment, where delicacy of movement is required, as in the setting of cores, closing of flasks, etc., is remarkable both for its perfection and for the ease with which the operation is performed. These movements may be, and frequently are, directed from below by the finger of the foreman.

In the electric system, one or motors on the bridge or trolley are supplied with current from a dynamo by means

of an overhead wire running the length of the building. By touching a few simple levers, or hand wheels, the wheels of the bridge are caused to revolve, the trolley-car itself is caused to travel back and forth on its cross-tracks, and the grooved drum carrying the chain and hook is caused to rotate, raising or lowering the hook, all of these motions being performed either at the same time or separately, in the same direction or in opposite directions, at the same speed or at different speeds, fast or slow, without confusion, by one man of ordinary intelligence. The operators are usually chosen from the ranks of unskilled labor, and are soon taught the simple movements. The levers are so arranged that the necessary as well as natural movements of the operator are in the direction he wishes the object to go, thus relieving him of embarrassment or uncertainty.

Coast Industrial Notes.

JOSEPH SNOW, of Newtown, El Dorado county, found a diamond in his mine while panning out black sand from the riffles in the flume. It is of a light straw color, of good form for cutting, and estimated to be worth between \$50 and \$60. On Tuesday another diamond of about the same description was found at Smith's Flax in the same county by Thomas Murdock. This diamond was valued at from \$25 to \$30.

PROFESSOR W. B. RISING opened his summer school in chemistry at the State University last week. The course is especially designed for teachers and others who are engaged at other seasons of the year. There are elementary and advanced courses offered, and a certificate of proficiency will be given to those who distinguish themselves by their daily work and who pass a satisfactory examination at the close of the season.

BUTTE COUNTY is considering the proposition of borrowing or raising \$500,000 to expend upon her roads in the next three years or so. The present conditions of the roads in most valley and foothill countries, such as Butte, operate to lessen land values, make rural life undesirable, discourage production by cost of carriage to rail market, repel immigration and generally to check and stay progress. The Butte papers tell us that the county expends \$42,000 annually upon road work that is annually pretty nearly all wiped out.

COMMODORE FARQUHAR, chief of the bureau of yards and docks of the United States Navy, is making a semi-official inspection of the yard and docks at Mare Island. During his visit Commodore Farquhar will select a site for the proposed additional dock to be located at the Mare Island Navy Yard, suitable for the accommodation of the largest warships. The big dock already there has only been completed a few years, but the modern vessels are so large that it has not suitable capacity in all cases. The new dock is to be fitted for taking in the largest war vessels of modern types.

THE Harbor Commissioners have let the \$100,000 cement contract. The material is to be delivered in three lots, of 13,500 barrels each, and the bid was to be so much a barrel on each lot. The contract was awarded to the J. D. Spreckels & Bros'. Company, who offered to supply the first two lots at a uniform price of \$2.40 a barrel, and the third at an advance of five cents. J. W. Grace & Co. offered to supply the first 13,500 barrels at \$2.30 and the second at \$2.35. They made no bid on the third lot, so their offer was thrown out. The only other offer was from Cowell & Co., who offered to supply the whole quantity at a uniform rate of \$2.70 a barrel. The cement is to be used for the foundations of the new depot at the foot of Market street.

THE crusade of Labor Commissioner Watts against the violation of health laws in local bakeries is bearing good fruit. When he and his assistant, Thomas B. O'Brien, made their first tour of inspection most of the places visited were filthy in the extreme. Every law on the books which has even the slightest reference to the matter was openly violated, and proprietors were notified at once to clean their places and put them in proper condition. Mr. O'Brien has made his second visit and the change made in those places where owners were warned is radical. They are clean and well kept. In some new floors have been laid. In others whitewash and paint has been unsparingly applied, and in almost every place evidence is given that the law is to be obeyed.

Foundry Notes.

THE heavy discount on silver has a material effect on the volume of business at our local foundries. Silver mining being so depressed, few, if any, new mines are being opened, and many old ones have stopped running. This, of course, naturally lessens the demand for machinery of all kinds. We heard of an instance of a Mexican mine the other day, which was to be equipped with a plant to cost \$130,000, but when they came to figure on the discount on silver, it was to cost so many thousands more that the project was abandoned and the expected job did not come to this city. Silver mines take more machinery than gold mines, for there are pans, settlers, etc., in addition to the stamps, and with dullness in silver mining there is bound to be dullness in the mining machinery trade.

IT IS EXPECTED that the ferry steamer Tiburon, which is being rebuilt at the Union Iron Works, will be ready for service about the 20th inst., and will be put back on the ferry route between here and Tiburon. A number of improvements have been made on her. The steamer was partly destroyed by fire last New Year's day while lying at the slip at the foot of Clay street.

Interest.

TO THE EDITOR:—Is interest just? Henry George, "the San Francisco Prophet," says it is, and some other economists say the same. There are, however, some facts connected with the subject which tend to inspire distrust of their opinions. Firstly, the learned gentlemen do not agree as to what it is which constitutes the justification of interest; secondly, they offer no explanation of the obvious and undeniable injustice of some of its results.

One of them justifies it on the ground of the self-denial practiced by the creditor, who might himself enjoy the use of his wealth; another, who has perhaps observed that in many cases the creditor, or money-lender, does not know what else to do with his surplus wealth, having more than he can enjoy, and, in other cases, it is only the man's credit, not money nor goods, that is loaned, and is not thereby diminished in any sensible degree, puts it a little differently, saying that, since wealth in some forms (as in pigs, for instance) has the power of self-increase, so wealth that is loaned, instead of being invested in some such way, should also increase. He seems to forget that pigs cannot exist, to say nothing of increasing, without the conjunction of land; that labor is also necessary to profitable increase; that it would not be possible to invest all wealth in such forms; and, worst of all for him (H. George), that the legitimate gain from the increase, on the average, cannot more than compensate the ground-rent, risk, knowledge, skill and labor.

Another finds the justification in the alleged fact that the thing which one has to-day is worth more than the similar thing which one will have after a certain lapse of time, the more being interest. This, at first sight, looks like our old acquaintance, "One bird in the hand is worth two in the bush," but there is a distinct difference. The gist of the adage is the certainty of possession of the one, and the uncertainty of catching the two, whilst the money-lender usually takes good care not to part with his one without such security as ensures the subsequent receipt of more than one. When credit is given without good security the case is different; the extra return then has the justification of risk, but to that extent it is not interest, though usually included in the rate—it is insurance.

It does not seem to have occurred to this philosopher that, if that which one has to-day is worth more than that equal thing which one is sure of having in a year hence, if he shall live to have, it is equally clear, if not clearer, that what one has to-day is worth more than the similar thing which one had a year ago, and hence that the two mores produce equilibrium, nor that it may be worth something to have his wealth taken care of for a year. Money, for it comes to money at last, is not like the plane which John lent to Thomas, about which a good deal was written by a great economist, liable to deterioration by wear, or to be mislaid, lost, or broken. The man who lends \$100 on good security to-day is humanly sure of receiving the equal amount, without loss or detriment, when it shall be due. Certainly the purchasing power of money may change meanwhile; it may rise, which will benefit him, or it may fall, to his loss, but that has nothing to do with our question.

The theory of Turgot is that interest accrues to capital because a person may invest in either land or capital. If he invests in land he can get rent, consequently he will not invest in capital unless he can get a profit on capital—that is, interest. (The reader must understand that these learned gentlemen, or most of them, do not consider money as being capital.) Böhm-Bawerk sees the matter differently, saying that Turgot has confounded the result with the cause. Capital and land are interchangeable because both have the inherent power of bringing an income, whatever may be the cause of that power, so we must find the cause for capital interest in an inherent power of capital.

And so it seems, according to this German *savant*, that poor little *man* has nothing to do with it all, except to get some land or capital, and "inherent power" will do the rest. I suppose it's very disrespectful, but really I can't help laughing. I wonder how much lager beer, tobacco and gray matter were expended in arriving at that lucid conclusion! I suggest that the Professor put some "capital," say limburger cheese, in a closet and see what the inherent power will develop in a year.

The argument of Turgot, who is I assume a Frenchman and therefore wrong from a German point of view, is certainly the more practical. If he can buy land that is worth buying, he certainly can get rent, more's the pity; but I confess that the fact does not appeal to my reasoning power as a justification of interest. However, it may be that the gentleman did not mean to justify but only to explain.

The practice of taking interest is as old as history, probably much older, and the discussion of its justice may well have begun soon after the first savage who was too lazy to climb a coconut tree for his breakfast borrowed a few nuts from his more industrious neighbor, on his promise to return a greater number the next day, which promise he probably failed to fulfill unless the other savage was bigger than he, and this, or something like it, gave rise to the device of giving security enough to cover both debt and interest.

I have been reading a rather interesting book on "The History and Theory of Money," by Sidney Sherwood, Ph. D., from which I obtained some of the foregoing statements, and from which I also learn that several of the ideas which I have expressed in former letters on and around the subject of money have been expressed before by greater men. This, while not flattering to me on the score of originality, though I still claim a little, yet affords me the consolation of knowing that, in so far at least, I am not a greater fool than some of my betters.

Mr. Sherwood shows that, as a few of your readers may know, Moses forbade the taking of interest from a Jew by a Jew, though of course it was lawful for the chosen people to plunder the Gentiles whenever they got a chance. He also says that the Babylonian Tablets show lending on interest to have been common. Aristotle, he says, argued that interest was not lawful (just, or right) because money

was barren and could not produce other money. (We are in the habit of saying, "Money makes money.") The Church very early made it unlawful to take interest for money from anybody; this prohibition was afterward limited mainly to the clergy, yet it was a long time before the taking of interest was legalized for the citizens of the chief European nations.

Thomas Aquinas was very sure that the practice ought to be forbidden. Aquinas made the curious discovery that money is consumed in the using, in which it differs from some other goods—a house, for instance—and he says it is right to charge for the use of such goods as a house, but if one lets a man take money the man uses that in trade, the money is gone, there is no more use to that man in the money, its value is consumed in the using; therefore if the lender makes him pay back not only that amount but also something more, he is doing an injustice.

I cannot help wondering if Mr. Aquinas was a writer for a comic paper; if not, he ought certainly to have shown cause why the debtor should pay back even one cent of the money that was "gone."

Mr. Sherwood points out a difference between the lending of money in the Old World and in the Modern World, namely, that in the former money was borrowed mostly by needy people for their personal use, while in the latter it is, to a great extent, borrowed for the purpose of profitable investment, so, he remarks, there was more justification for the prohibition in the Old World than there was later.

As to that, I remark that the same difference exists now, not only between different countries but also between different classes of borrowers among ourselves; yet it is not practicable for the law to discriminate, whatever individuals may do.

The taking of interest seems to have been generally condemned by the greatest writers of all times up to that of the revival of commerce following the discovery of America, and especially of the rich silver mines of Peru, which raised prices enormously and gave a great impetus to enterprise; then, says Mr. Sherwood, writers began to defend it.

David Hume, about the middle of the 17th century, showed (?) that interest was not paid for money primarily, but for capital; that what the person who borrowed money wanted was not the money itself, but the instruments of production which he used in his business.

With all respect to the memory of a talented man, I beg to remark that his reasoning impresses me as being simply bosh, as much so as that of Mr. Aquinas from whose book he seems to have taken about half a leaf. When a man borrows money he does so because he wants to use it in some way, not merely to look at it, and the simple question is, ought he to pay interest?

I can gain little or no insight as to this question by reading books. Those economists who defend interest seem to have approached the subject rather with a view to finding a reason for a foregone conclusion than of probing the validity of that conclusion. Apparently they have not asked themselves "Is interest just?" but, taking its justice for granted, have simply tried to show why it exists, as Newton, seeing an apple fall, asked himself, not "Will an unsupported apple fall?" but "Why does it fall?" and, as usual, the learned gentlemen have fished in deep water for pearls of poor quality, and missed the purer gem which they might have picked up on the shore. Or is it that, like Bramah, they were absorbed in the contemplation of their own perfection, and so did not know an oyster from a clam?

It is not worth while to consider the popular fallacy that "money makes money" as a justification of interest. Let old Aristotle and Aquinas answer that. Perhaps the next most obvious plea, to the superficial view, consists in the fact (?) that interest is a simple matter of agreement between free contracting parties; that it is paid voluntarily by the debtor. In truth, however, this argument might equally apply to the case of the traveler who hands his purse to the highwayman voluntarily—under the circumstances—said circumstances being the apparition of a determined fellow and a cocked pistol, for really, in a certain class of cases, the willingness of the borrower to pay interest is the product of circumstances scarcely less convincing. The argument is applicable, however, to those cases in which money is borrowed for speculative purposes.

Another plausible justification, at least of paying if not of taking interest, is the sad plea of the borrower, that he can't get the money unless he does so. This, however, does not satisfy the ethical consideration; there must be right on both sides or there is not justice. No one blames the traveler for yielding up his purse to the armed robber, nor does any right-minded person exonerate the robber from blame.

Victor Hugo, in *Les Misérables*, tells a sad history of a mother selling her beautiful front teeth to secure, as she thought, protection for her Cosette; she could only be admired for her heroic sacrifice, the more so as her beauty was her livelihood, but that does not prevent us from execrating the villain who drove her to it, even though he had not further involved his infamy to the one-hundredth power by stealing the money.

Some writers have preferred to treat this question from the standpoint of some commodity, such as a plane or a house. I think it simpler to treat it on the basis of money, partly because interest is always stated in terms of money, and paid in money (or credit, which is the same for our purpose), and partly because we thus eliminate certain complications. But it must be understood that it is not the body of money with which we need to deal in considering the intrinsic question, but what, if I were inclined to be poetical in such matters, I might call the soul, which is credit. He that receives paper money receives the promise of the issuer, and he that receives gold money receives the promise of the world, that the service for which the money was given shall be returned. It is this "inward and spiritual grace," of which the coin or paper is "the outward and visible sign," with which we have to deal at present. Money is the representative and synonym of all kinds of service.

I shall continue this subject in another letter.

C. H. AARON.

Mining Royalties in Great Britain.

The British Royal Commission on Mining Royalties has just made its final report. This report is a unanimous one, which is all the more remarkable when we consider the apparently conflicting interests that made up the commission.

Many of the facts brought out in this paper are of interest to our mining industries and show the different conditions that exist, especially in coal and iron-ore mining of the United States and Great Britain. In the latter country much of the coal and ore land is entailed and is held by the large landlords, usually the nobility, or some religious, educational or similar foundation. The right to mine is leased on royalty.

In the United States, on the other hand, until quite recently, most of the coal and ore mined was produced by the owners of the land. In the last few years, especially in the coal mines of Pennsylvania and West Virginia, and the iron-ore mines of Lake Superior and other regions, an increasing amount of coal and iron is mined on royalty.

In Great Britain the time limit of mining leases varies from 21 to 63 years. A fixed rent is usually payable, merging, however, into the royalty rent. Royalties are generally a fixed sum per ton, but sometimes they vary with the price of coal. Where the amount payable for royalty upon coal raised in any year is less than the fixed rent, the difference is known by the term "shorts." Lessees often have the right to work out coal paid for as shorts in subsequent years. Sometimes a lease contains a power to surrender, and, as a rule, a lessee is prohibited assigning without the permission of the lessor. Special prominence is given to "wayleaves." A wayleave is a leave to pass over or under land not included in the mining lease. For this leave the owner exacts a payment, generally of a penny per ton, but he has the right of refusing any leave whatever.

The estimated total royalty payable in 1889 on coal was just over £4,000,000, and the estimated wayleave charges were over £200,000, making a total of £4,200,000. Taking the total output for the year as 177,000,000 tons, the royalty and wayleave is equivalent to rather more than fivepence per ton. As regards iron ore, the royalty is estimated at £561,000 on 14,500,000 tons, about 9½d. The estimated royalty for all other metals—e. g., copper, tin, lead, etc.—is estimated at £87,068.

But little information as to the amount of royalties paid in the United States is available. All coal mined in the Flat Top (W. Va.) region is mined on a royalty of 10c a ton, and this seems to be the usual rate in the bituminous mines of Virginia, West Virginia and Pennsylvania. In the Connellsville region there are some royalties as low as 7c a ton and some as high as 11c, but 15c a ton of coke, which is equal to about 10c a ton of coal, is the usual royalty. In the anthracite region the royalty is much higher than this; 20c is not unusual, even 40c has been paid.

Iron ore royalties vary greatly, but 20c to 30c a ton is not unusual. In the Mesabi range 40c and even 65c is paid, and 40c is not uncommon in other districts. Leases are usually made with a minimum amount to be paid each year, and, so far as we know, no "shorts" are allowed. There are leases, however, that provide for reductions in the tonnage royalty when the amounts paid exceed a certain sum.

The leading objections brought out by the British Royal Commission to the system and methods of that country were (1) that royalties were too high, (2) that "shorts" and unexhausted improvements are confiscated, (3) that the restraints and alienation and surrender of mining leases are too severe, and (4) that the powers of land owners enable them to exact heavy wayleaves. Further, it was alleged that copy holders abuse their rights, and that the powers of limited owners to lease their mining property was not sufficiently extensive.

The result of the inquiry is that the commissions do not think that any legislative interference with the amount of royalties is desirable, though they recommend the general adoption of the principle of varying royalties by a sliding scale, but they recommend the establishment of a tribunal for dealing with wayleaves; they approve of the organization of a Department of Mines in connection with the Home Office; they think greater facilities for leasing mines should be given to corporations and life tenants; and they further recommended that the power possessed by copy holders and surface owners of preventing minerals being worked should be checked.

Incidentally the question of the nationalization of minerals was raised, but it did not meet with much favor. The miners' representatives did not favor it, and the commission reported:

"No suggestion in favor of the nationalization of minerals was made by any of the associations representing lessees, and those witnesses whom we examined on behalf of lessees who were questioned on the subject expressed a decided preference for the present condition of the law of mineral property. In these circumstances, and as the nationalization of minerals is only a portion of the larger question of the nationalization of land, we do not consider that it is necessary to discuss the matter further."

At Floriston, Meadow Lake township, Nevada county, the new mill will soon be running at its full capacity. An 80-horse-power donkey engine has been ordered with which to log, particularly to snake logs from the most abrupt mountain sides to the shutes on the top of the mountain. The mill will cut snowshed timber for the S. P. Co., in addition to the manufacture of lumber for market. Some improvements are being talked of to increase the cutting capacity of the mill so that it will cut 40,000 feet per day. Mr. E. G. Sukeforth will have charge of the mill, while the mill has been leased by Mr. Sukeforth and S. H. Simonds. Mr. Bixby, an old experienced logger who has been logging in the Redwoods and in the Puget Sound country, will have charge of the logging camp.

The Mines at Angels, Calaveras County.

From Our Own Correspondent.

TO THE EDITOR:—Angels is to-day one of the best mining towns on the mother lode; at the same time it is not what it will be or might be at this time. Merchants and landlords all complain of dull times from an excess of stores, hotels and saloons. The trouble, however, is not so much the overtrading as it is the class of miners employed. These are largely Italian, Cornish and Austrian—good miners, but of little benefit to a mining town, as they spend but very little of their earnings, and that among themselves. If the mines were manned by Americans who would build homes, make their permanent residence in the town, and invest their earnings in local enterprises, and in surrounding their families with all the comforts that the American will have when his purse will afford it, Angels would boom in trade as well as mines. At the same time there is a large volume of trade, and it is only a question of a short time until, with the steadily increasing population, Angels will be the mining town of the State. The closing down of Nevada's mines has set adrift a large number of miners who drift all along the foothill mines of this State in search of employment. Angels is overrun with them. Many of these men are of no account, while among them are some first-class miners and deserving men. I met a miner at the Gladstone mine, Shasta county, who had walked there from Nevada. A few months later I met this same miner near the Sheep Ranch mine, in Calaveras county. He informed me that since last seeing me he had footed it up through the mines of southern Oregon, then back and down through Del Norte, Siskiyou, Trinity, Shasta, Butte, Nevada, Placer, El Dorado, Amador, across the lower part of Calaveras, through Tuolumne and back across Calaveras to the point where I met him, and had failed to find a job. Now he was a hale, hearty miner, a man of more than ordinary intelligence, and acquainted with many of the mining superintendents along the route he had taken, but he had failed to find a day's work. I presume this is but a sample case. If this or any other miner would remain in one mining town until they were known and found reliable, I doubt their having to move on. It is to be hoped that the starting up of the gravel mines will in some degree absorb this vast army of unemployed miners.

Few would believe how great their number is, and unless some employment is afforded them, it will be but a question of time until crime will follow on this track, for men must live, honorably if they can, but live they will. The furnishing of employment to this vast number of unemployed miners is a question that should interest every mining man in a solution of this grave question. At a distance it may seem exaggerated, but all along the roads, and in the mining towns, I meet miners who ask me where they can go to find work, while every mining superintendent states that he is overrun with miners seeking work; that they offer to work for their board, and that the number is constantly increasing. Angels seems to be the Mecca to which they drift, only to find every mine full-handed.

Angels, as is well known, is on the mother lode and the mine owners all claim to be on the *true* mother lode. They remind me of Sam McMaster when I asked him how wide the Homestake vein was at Deadwood and he replied, "I've been across the country for 80 miles and haven't found either wall." The mineral zone at Angels is about three miles wide. In this belt are a large number of developed and undeveloped mines, though the greater portion of the ground is held under agricultural patents and used as a stock range. The mother lode affords a very interesting study that grows in interest as you follow it up. It has been the lot of the writer to travel up and down on the line of the mother lode and to inspect the leading mines on the vein for years past, and while much has become an "old, old story," there is constantly new features cropping out that open up new fields for investigation and serve to keep the interest from flagging. It is pretty generally admitted that there are two veins while there is no doubt about the value of either. The lode is only credited with a length of 80 miles, but can undoubtedly be located for almost twice that distance. The main, or eastern vein, is usually found near the apex of the hills, through which it courses; while the west vein lays along the base of the hills to the west. In consequence of their location the country rock over the eastern vein has been greatly shattered and numerous gash veins and "quartz crossings" have been formed which, as a rule, are the source of the pockets on the mother lode.

The west vein is covered by the overlying hill and holds its wealth within its walls and is generally a good milling proposition wherever an ore shoot can be found. The vein's appearance varies with the formation through which it passes, and in consequence while in the talc and porphyritic green slates of Mariposa, Tuolumne and Calaveras, the vein is made up of irregular parallel plates of white compact quartz mixed with green talc. This is given as the auriferous portion of the lode by Prof. Whitney, but active working does not prove this to be the case, as the greater portion of the gold extracted comes from the talcose slate bodies that accompany the white quartz and are found on one or both walls. At Angels there is found both the talc slate veins and also the ribbon quartz of Amador county mines.

The talc veins cross Angels, while the black graphite slate belt of the ribbon quartz is about one-half mile west. In Angels the mother lode strives to give all a choice for a location and spreads out like the ribs of a fan with occasional crosses. The main branch of the mother lode comes up from Carson to Angels' creek, with a stony cropping. At this point it drops out of sight. Once across the creek it crops boldly into what is known as the Johnnie Meyers mine, and then runs north through the Coleman property; crosses above Altaville and runs under the gravel on McElroy's old gravel claim. The slate through which the vein passes can be found at the foot of French Gulch, about a half a mile above Dogtown and several miles north of Angels. All along the east of this vein there has been worked

from the early history of the town to the present time, successive strata of mineralized talc slate. In this section is the well known Utica mine which occurs as a gash vein, but proves none the less valuable. At Angels creek another branch crops boldly with the Madison, Gold Cliff and Suffolk mines on its course. By some it is contended that the lode makes an abrupt angle and turns from its course at this point, instead of dipping under, and that the true vein is that on which the Madison is located. West of these veins and swinging rapidly to the west, are a number of veins which are, no doubt, connected with the mother lode if not on it, while about a half a mile distant is a strong vein of ribbon quartz that looks like the *true* west branch of the mother lode.

In Amador and El Dorado it would be called the true lode. Between these ledges and beyond them for a width of three miles are mineralized bodies of talc slate and numerous quartz ledges. The whole section might well be called one vast segregated vein. In consequence of the great area here mineralized, the future of this section is one of great possibilities. The average of the ore is low in grade but easily milled, and the solution of the future working of this immense belt to a profit is in a large number of stamps with competent and economical management.

THE UTICA MINE.—Hayward, the Hohart estate and Lane are proprietors of this property. It is the leading one of the town. The plant is extensive and embraces a complete water system known as the Union Water Co.'s ditch and reservoirs, the Utica and Stickle mine, with the Angels Chlorination Works. In addition to the company's two 60-stamp mills they have their own sawmill, machine shops and silver-plating works, making a very extensive and complete plant. The Utica Company is also interested in other mines in the camp, all of which are under the charge of the genial owner Charlie Lane. The Utica mine proper is in charge of Mr. Lane's son Thomas. The mine has two shafts—600 and 900 feet deep—with a 60-stamp mill run by water-power. The mill is in charge of Mr. Hayward's old millman, John Reeves, and is run "like a clock." Nothing has been omitted that can in any way improve the working of the mine or mill. The 60 stamps feed their ore over long stretches of plates. The pulp then passes to the 24 Frue concentrators and thence a half-mile down the creek to a large building with a floor of canvas, where the finer mineral that escapes from the concentrators is caught. The air-compressor is one of the largest in the State and furnishes power for all the drills in both the Utica and Stickle. At the shafts the Fuller skips and safeties are used. The ore-skip dumps its ore in such a manner that it is impossible for any of the ore to fall back into the shaft. The water skip discharges its water through a side-valve, thus allowing the skip to hang vertical at all times, and not only saves wear but prevents accidents. Over the skip is placed the Fuller safeties, which, since they have been in use, have saved the life of the manager, Chas. Lane, and that of a number of miners. This safety acts on the parachute principle and is positive in its action. The least drop of the skip at an unusual speed causes the parachute to rise and instantly engages the dogs. The safety, however, has a feature peculiar to itself in this: that the miner on the skip can instantly stop it at any point in the shaft. If there is ever a law enacted compelling all mines to use safeties, as there is now for car-couplers on railroads, the Fuller safety will, I think, be the one adopted.

A NEW HOIST.—On the Stickle the old hoist has been removed and sent up to the new purchase at Shingle Springs, El Dorado county. In its place a hoist to go 2000 feet is now in operation. This hoist is from the works of Demarest & Fuller of Angels. While there are very fine hoists on both of the Utica shafts, this hoist on the 900-foot shaft of the Stickle is far superior, and I doubt its being excelled by any hoist in the State. It is run by water power and operated by two small hand levers. The hoist seems out of proportion, with its immense gearing and the slight, simple lever system that opens and shuts the water valves, and is in striking contrast with the usual array of heavy levers and brakes that look confusing to the uninitiated. This hoist is attracting the attention of mining superintendents throughout the State, and will no doubt be duplicated elsewhere. The shaft is equipped with the Fuller skips and safeties. The mine is connected on each level down to 900 feet with the south shaft on the Utica. The mill is a 60 stamp, and is in charge of James Leonard. The mill is Mr. Hayward's latest, and in the mill as well as in the hoist everything is of the latest improvement and best patents at this time. The plan of the mill differs somewhat from that of the Utica, and, taken as a whole, can hardly be improved upon.

For this mill several forms of concentrators were given a thorough competitive test, and the order given Demarest & Fuller for 16 Tullock concentrators to fill out the mill's equipment. These concentrators have been fully described in former issues of the PRESS, but have been greatly improved in almost every way by Messrs. Demarest & Fuller, until, in the opinion of those in authority, at this time, their capacity is the greatest, product unusually clean, loss the smallest and cost the lowest of any machine tested.

THE ANGELS CHLORINATION WORKS.—This is an extensive and complete plant, consisting of two ovens, each 14x80 feet, with a daily capacity of eight tons. The works are in charge of Mr. T. M. Smith. It is reported that the cyanide process will be tested on the sulphurets of the camp at the chlorination works, and, if found a success, that a cyanide plant will be erected. It is well known that Mr. Hayward's motto is, "D— the per cents! Give me the dollars and cents," and should he adopt the cyanide process there will be no further doubt of its working success.

THE MADISON MINE.—T. Lane is superintendent and Naylor Williams foreman. This mine is the property of Mr. J. T. Lane and is being developed under bond by Messrs. Hayward & Lane, who have secured this and a number of adjoining mines. The shaft is being put down as fast as men can sink it, and is now 800 feet deep in the

footwall with crosscuts of 30 feet at each level to the vein. The shaft is put down a hundred feet, when the mines in the drift above come down to start new drifts, which are continued until the next 100 feet is sunk, when the drift is left and the miners go down to the next level. Every effort is made to crowd the shaft down. The ten miners in the drifts keep the 20 stamps dropping steadily. The ore-body milled is about 20 feet wide. The white quartz is left standing as a hanging-wall, being barren of mineral, Mr. Hayward believes that "no footwall, no mine," and is sinking to get a footwall to suit him and have the mine so thoroughly developed that, once they start milling, they will have sufficient ore in sight to keep 100 stamps dropping. This is the only way to operate on the mother lode at Angels or elsewhere. These companies that buy mother-lode mines, and at once set up a mill and expect dividends from the grass roots, are in the wrong location and business as well. Every mine on the mother lode should be given two years of pushing development before erecting its permanent mill, and the owners should expect to put in the mine all the capital needed for another year before expecting any returns. Under practical mining superintendents' charge, few mother-lode mines will fail to yield very satisfactory returns when thus managed.

GOLD CLIFF.—J. Woodson Garrard is superintendent of the Gold Cliff, which is opened about 75 feet across the vein by a crosscut tunnel and a large open face at the mouth of the tunnel where the ore is quarried out 75 feet across and 100 feet high. Mr. Garrard keeps the 20 stamps dropping at a cost of 65 cents a ton for mining and milling, and could reduce this if he had the 100 stamps the mine would supply. The mine is under bond to Hayward & Lane.

BROWN, SMYTHE & RYLAND MINING CO.—C. D. Smythe is superintendent of the group of mines which was formerly known as the Suffolk. At this time a crosscut tunnel is being driven to drain the surface water. The mine has been worked in former years, and the quartz I found to be the highest in value of any mine in the camp, but rebellious in character. It is Mr. Smythe's intention to test by pan amalgamation and the cyanide process.

ECLIPSE.—The Eclipse, T. E. Flagg superintendent, is about a mile west of Angels and just east of the old Osborn mine. The old shaft has been stopped, and Mr. Flagg has put down a shaft north from which he is cross-cutting through very hard rock, and is in about 100 feet in talc, slate and quartz, all of which is considered good milling ore.

GOLD HILL MINING CO.—S. V. Ryland is general manager. This is the old Osborn mine, and is located about three-fourths of a mile west of Angels. The mine is opened by a series of shafts, crosscuts, drifts and open cuts. At present a fine shaft is being put down north with levels run to the veins, which so far show 15 and 20 feet of milling ore. On the surface the entire hill is mineralized, and its earlier workings produced over \$100,000 in heavy gold. Mr. Ryland has purchased at Denver a complete cyanide plant, which he expects to erect soon in addition to the present ten-stamp mill. The owners are Chicago capitalists.

COLEMAN'S MINES.—These mines are in charge of Mr. Coleman's friend, Mr. G. H. Fox. The property is very extensive and is said to be evenly mineralized throughout. At present a few tributaries are taking out ore from a point at the north end of the mine. Every now and then it is reported that Mr. Coleman will start the mine, but so far he has not done so. With the large area to draw on the mine could keep 500 stamps dropping steadily.

THE PIONEER.—D. D. Demarest, owner—is being pumped out, and once it is open for inspection capital will investigate and if satisfactory, invest. This property carries the largest per cent of sulphurets of any mine in Angels and, if developed, should prove a good mine.

THE DEMAREST MINE.—D. D. Demarest, proprietor—is in the Hawkeye district, about five miles west of Angels, and on the mother lode. The mine is opened by a 120 foot shaft. The vein is from two to five feet in width that has milled \$12 per ton. In the bottom of the shaft an additional vein is coming in that promises equally well. The mine is a very fine prospect and is for sale.

THE THORPE MINE.—Moses Thorpe, owner—is near the Demarest. The shaft is down 107 feet with a drift run 140 feet on a vein that goes \$6 to \$16 a ton and is from five to ten feet wide. There is an old relic of a mill and hoist on the mine.

CHEROKEE.—B. R. Prince, owner.—The Cherokee is about one-half mile N. W. of Angels and was a very rich mine in heavy gold having a variously estimated value up to \$800,000. It is a difficult matter to determine the amount. Mr. Prince took out one pocket of \$60,000 after he came into possession. A fire destroyed a miner's cabin while the miner was down in the mine and in the ashes was found an old-style square 10-pound lard can filled with gold. Just how much more was appropriated in this way it is difficult to determine. Mr. McKenzie has a bond on the mine and will no doubt take the property, as his work shows on the east end a large body of good milling ore in addition to the showing at the shaft.

THE CALIFORNIA CONS.—Curtiss, Hendricks & Atkinson, owners—is west of Angels about one and one-half miles. It is opened by a crosscut tunnel, 320 feet long, that cuts the vein 110 feet deep. The vein is here 65 feet wide, of fine ribbon quartz similar to the mother-lode mines of Amador county. There is a shaft down on another vein five feet in width, and a tunnel on the opposite side of the hill cutting another vein 12 feet wide. The mines cover four full claims of 600 x 1500 feet each. If this mine had a shaft 1000 feet deep there is everything to show that it would prove a fine property and start a boom on this branch of the mother lode at Angels.

THE JOHN L., owned by S. V. Ryland, joins the California Consolidated on the south and is opened by a shaft 70 feet deep on a 12-foot vein.

BREUNER, BOLITHO AND GRAHAM.—These three mines have been bonded by J. M. Breezen for Denver capitalists. The Bolitho shows very rich rock spangled with gold.

Sufficient work has been done in the past on all of the mines to show them to be good propositions.

CARSON CREEK MINING CO., E. W. Roberts superintendent, is the old "Doc Jones mine," and is located on the west branch of the mother lode on Carson creek and about a mile west of Carson. The shaft is now down 300 feet with crosscut run 70 feet and no wall reached. The ore in the bottom of the shaft carries silver tellurides and gives the mine the highest silver record of any mine on the mother lode. The free gold is small in value, but the high-grade sulphurets more than make up for this. On the hanging-wall there is a vein carrying 30 per cent of iron sulphurets that go \$90 a ton, while the foot-wall vein carries silver telluride and sulphurets that go \$950 a ton. The per cent of silver is from 25 to 50 per cent of the value. The mine is equipped with a 40-stamp mill running under 350 feet of water pressure. Everything would indicate that the Carson Creek was not only a coming but a present mine of great promise, and under the present efficient superintendent will, when thoroughly developed, prove one of the leading mines of the district. The property is owned by Porter, Remington & Gates, the well-known paper manufacturers of New York.

THE ALLISON MINE.—Robert Allison is owner of this mine. The property is 600x300. It joins the Carson Creek on the south. The mine is opened by a crosscut tunnel that shows a fine-looking ledge on the foot-wall to the south. The tunnel has been extended 45 feet across the vein through gangue matter and the hanging-wall not reached. Mr. Allison has been given very high returns both from the vein and gangue. The position of the mine is such that it should, when developed, show ore similar in value and character to its neighbor, the Carson Creek. The mine wants a 500-foot shaft and crosscut and is open for investment.

There is nothing doing at Carson. Over on the river the Calaveras Con. G. M. Co. is said to have settled its differences and will soon start up. E. H. SCHAEFFLE.

What Is Lignite?

A correspondent of the *Colliery Guardian* says: The answer given to the above question by "M," in your January issue, is an admirable resume of the distinctions between lignite, or brown coal, and bituminous coal, as to physical and commercial characteristics.

Mr. Symington, in your April issue, asks "the dividing line between lignites and so-called bituminous coals as shown by their commercial analysis." To illustrate his meaning he gives four analyses, saying that one represents the composition of a coal from true carboniferous measures (presumably bituminous coal), the other three being analyses of cretaceous coals (presumably lignites); then he asks, "Which are lignites?"

It is quite impossible to tell from the analyses given which are lignite. In fact, the ordinary commercial analysis, reporting the composition of a coal in terms of water, volatile matter, fixed carbon, sulphur and ash, entirely fails to give any data for forming an opinion on this point.

The distinction between lignite and bituminous coal, aside from the physical differences of structure, color, and weathering qualities, is based upon the amount of oxygen contained therein, exclusive of ash and water.

It is now generally accepted that all coals consist chiefly of oxygenated hydro-carbons, with, in some instances, a small percentage of hydro-carbon containing no oxygen, and of pure carbon.

The mechanically combined water and the ash, depending, as they do, upon the local conditions attending the deposition of the coal, are eliminated from consideration in determining the mineralogical character of a coal.

Drying the sample of coal at 100 degrees C., and subjecting the remainder to ultimate analysis, and obtaining the result in terms of hydrogen, oxygen, nitrogen, carbon, sulphur and ash, we have the data for determining the mineral character of the coal.

Thus analyzed, a bituminous coal will yield from 5 to 15, rarely as high as 17, per cent of oxygen, while a lignite will contain from 15 to 36 per cent.

Strictly speaking, while the terms lignite and brown coal are usually used interchangeably, and do indeed refer to chemically identical substances, the use of the word lignite should more properly be restricted to that form of brown coal which retains the fibrous structure of the original wood.

Krupp's Workmen.

An interesting account of the methods pursued by the proprietors of the great Krupp foundries, at Essen in Germany, for the benefit of the workmen employed there and their families, is given in a recent number of the "Annals of the American Academy of Political and Social Science." The following is an abstract of the paper:

The Krupp works employ 16,000 men, and with their families, numbering over 50,000, constituting the bulk of the population of the town of Essen, while over 3000 are located at various branch works, and the total number benefited by their numerous charitable and philanthropic enterprises is estimated at 25,200 workmen, and with their families, 87,900 persons. The Krupps themselves say that their numerous institutions for their workmen and their families are based first on their own business interests. Their successful efforts to raise the condition of their workmen have been made in various ways. The Krupps have built over 4000 houses—from frame dwellings of two rooms, renting at \$15 a year, up to six-room houses, renting at \$80 a year; they have expended over \$3,000,000 on them, earning about two per cent on the investment, but this, with much more, has been spent in benefiting the working population in other ways.

The co-operative stores, managed by the Krupps at their own risk, include 15 retail grocery stores, nine branch stores, with one main store for general merchandise, a shoe factory with three stores, a hardware store, a mill and bakery with three bread stores, a slaughter house with

seven retail meat stores, two clothing establishments, seven restaurants, a wine store, an ice company, a coffee-roasting establishment—in them nearly 500 persons are employed, widows or daughters of workmen. There is a boarding house for the unmarried workmen, where lodging and food are supplied at 20 cents a day. In 1870 Alfred Krupp Krupp built a hospital for sick and wounded soldiers, and since the Franco-German war it has been used for their workmen and their families—they are cared for at the price of 38 cents a day for men, 30 cents for women and 25 cents for children. There is a large bathing establishment, where 6000 free baths were given last year, and bath tickets are sold for 2½ cents apiece. The insurance funds against accident and death and for pensions have been largely supplemented by the Krupps, in addition to the strict requirements of the German laws. Primary and advanced and technical schools are maintained by the Krupps, who say that all this is done to enable them to extend and improve their work by making their workmen sharers in their prosperity.

Comparison of Fans in the Ventilation of Coal Mines.

The very effective work now being done by different ventilating fans shows that furnace ventilation is going, gradually but completely, into disuse. At the present time very great attention is being given to the question of fan ventilation by engineers, and different constructors are pressing forward their claims to the merits of their fans.

One of the machines which has of late been introduced at English collieries for ventilation is that of Noel Chandler, which is a high-speed fan worked by the direct action of a quick-running engine. The fan is constructed of blades, having a modified form of S—the inner end being curved forward in the direction of rotation. According to the *Transactions of the Mining Institute of Scotland*, one of these fans 6½ feet in diameter and 2 feet 5 inches wide, at 265 revolutions per minute, gave at a recent experiment a quantity of 49,896 cubic feet of air per minute, with a water-gauge of 1.1 inch. Another of these fans, 10 feet diameter and 5 feet wide, worked by an engine of 26 inch cylinder and 13-inch stroke, at 867 revolutions per minute, produced 58,791 cubic feet of air per minute, with a water-gauge of 1.6 inches. In this case it was calculated that the useful effect of the fan was 70.13 per cent.

The Rev. G. M. Capell, who is an expert mechanical engineer, calculates that his fan will give a useful effect of 80 per cent. One of his machines now working at Prosper I colliery, Germany, is a 12 foot 3 inch double inlet fan, driven by two engines coupled, each 20½ inches by 32 inches stroke, with Rider expansion gear, giving up to 450-horse power. Another of these fans is working at Kingswood colliery, Bristol, which is 11 feet diameter, giving 61,560 cubic feet of air per minute with a water-gauge of 4.7 inches.

One of the Rateau fans, which is erected at Montrambert de la Beraudiere, 9 feet 2 inches diameter, gives 75,462 cubic feet, with a water-gauge of 2.7 inches. Mr. Capell, in comparing his with this, says he has fans giving 70 per cent of manometric effect at high gauges, but does not advise such high manometric effect. In experiments by the North of England Institute of Mining Engineers it was found that the Guibal fans gave the highest useful effects with from 52 to 54 per cent of manometric effect, which corresponded with his experience. With low speeds and high manometric effects the strain on the fan-shaft is greater. That this is the case Mr. Capell says is borne out by the report of the commission, for while the cost of lubricating the fan at Prosper colliery, giving 99,590 cubic feet of air at 6.10 inches water-gauge and 95.79-horse power in the air is only 0.15 franc a day, the cost of lubrication of a Rateau fan at Rieu du Cœur colliery, passing 46,615 cubic feet at 2.83 inches water-gauge or 20.83-horse power in the air, is put down at 0.65 franc per day. On these matters should be taken into account in making comparisons. To get a fair comparison of the actual results of different fans, a test committee should be appointed to experiment with the different fans to be tried, which should be placed under the same conditions, in the same fan casing, and be worked by the same engines.

HARDLY has the South Gila Canal Company commenced the great work of damming the Gila river and building a canal 125 miles in length, through one of the best portions of Arizona, and before the Sonora Canal Company has completed the survey for its canal in California, when another project of the utmost importance to Yuma and the great area of arable land lying to the south and east of Yuma, in Arizona and the Mexican State of Sonora, is inaugurated. The plan is to dam the Gila river at the gorge, twelve miles east of Yuma, and create a reservoir thirty miles in length and eight miles in width. The dam which will be of solid masonry, is to be 4500 feet in length and 110 feet high. It will extend from the mountains on one side of the Gila, to the opposite bank on a reef of bed rock where three small islands rise out of the bed of the stream. These islands will form abutments to the dam which will be built with such a slope as will carry the water away from the dam without cutting or wearing away the rock at its base. The flume, or canal, which will conduct the water away from this reservoir to the lands to be irrigated, will not be over a mile in length. From the end of the flume to the south and west, canals will be constructed over the mesa and valley lands in different directions when the lands, which all belong to the United States Government, are settled. The reservoir, it is estimated, will hold water enough to irrigate the 3,500,000 acres of land lying to the east and south of Yuma, which extends into the Mexican State of Sonora, and will also furnish water for 100,000 acres of the Sonora Land Company, lying between the dam and Colorado river, in the valley of the Gila. It is estimated that the dam alone will cost \$5,000,000, and that it will take two years to complete it.

South African Gold Mines.

South African gold shares are decidedly that class of security which amid the general depression of the stock and share markets offer by far the most tempting opening to purchasers. There are many reasons which combine to attract the public in this direction, says the London *Mining Journal*, apart from the actual position of the shares themselves. Australian affairs are so exceedingly gloomy as to discourage all speculation in that quarter, while elsewhere the blighting influence of the silver evil is severely experienced. Our South African colonies have never been guilty of the financial recklessness of South America and Australia, and there is a backbone of settled population there to support the new development of enterprise. Moreover, even the financial world has a Carlylean faculty of "hero worship," and imagination has been stimulated by the magical personality of the Cape Colony Premier, De Beers amalgamator, Chartered Company promoter, and Uganda telegraph constructor. In the absence of any reasonable prospect of an upward movement in other classes of scrip for at least some time to come, it is not, therefore, remarkable that South African enterprises, mineral and others, should be displaying so much animation. We believe, however, that the revival is based upon a much more solid and permanent cause than the general difficulty in finding channels for speculation. For a long time numerous prophets have been pointing, almost unheeded, to the revolution which has been effected in the methods of gold mining on the Witwatersrand, to the reforms which have taken place in company organization and personnel, and to the change in public policy which is reducing the cost of production. If the first Randt "boom" was the outcome of ignorant credulity, that which is now developing is the product of scientific assertion gradually working upon public scepticism. The most eminent mining experts have not hesitated to couple the acutest geological theories with the most glowing accounts of the Randt's future. The reef is of enormous extent, with ore poor in gold but remarkably uniform in character. There is thus the prospect of the development of the most surprising gold mining enterprise the world has ever seen—of an auriferous industry carried out on the same gigantic scale and with the same huge plants as the working of a coal field. In another couple of years the Randt alone may be producing £10,000,000 worth and thus by adding 50 per cent to the world's supply of the precious metal it will be solving one of the greatest economic problems. It is surprising to see the Randt output attain in March so heavy a total after the widespread stoppage of work caused by the floods in the previous month, and there can be no doubt that the general additions and improvements to plant which have resulted from that calamity will bring about a brilliant advance upon all previous records in the early future. The new developments which are taking place on the Randt are not confined to the extension of steady and scientific work to the deep levels. All the principal mines are now equipping themselves with rock-drilling plant, electricity is being generally used for lighting and power transmission, the value of the cyanide process has been conclusively proved, and is being generally adopted. Claims which, when formally worked, failed to pay under the disadvantages of exorbitant purchase money and wasteful methods are again being developed. The reported discovery of coal in the west Randt seems to open up a more promising future for the mines in that direction. Enterprise is again reviving on De Kaap field, while other new auriferous deposits are opening up all over the Transvaal. The new Silati railway will afford the possibility of profitable exploitation to mines of which most satisfactory accounts are published. As to the external influences of the gold mining industry few operators in the "Kaffir circus" probably have any conception of the extent of the change which has been wrought. The railway from the Cape Colony has had the effect of reducing appreciably the cost of mining materials in Johannesburg and by facilitating supplies has abolished altogether the temporary inflations which at one time were the rule in all commodities. This effect will be further exhibited when the railways, now in course of construction, are completed from Natal and from Portuguese territory. The labor question is still a difficulty, but it seems likely to vanish beneath one or both of two solutions—the one the compound system, the other the increased importation of white miners. As it is the reduction of liquor licenses in Johannesburg has done much to improve the position of the mining industry in respect to this important factor of labor. A further decrease in the cost of mining is promised in the abolition of the dynamite monopoly and the proposed cheapening of cement. There are, thus, many reasons why mines which have not hitherto paid dividends should be capable of remunerative working under these altered conditions, and it is not wonderful that prices should have risen, and that fresh capital should be asked for. Outside the Transvaal the gold mines of Mashonaland are attracting the most hopeful attention. The explorers are themselves thoroughly impressed with the auriferous value of their territory, and the more investigation is extended the more encouraging the reports become. It cannot be doubted that Mashonaland as a gold country has a big future before it. In Zululand promising work is being done by a syndicate, and a most eminent mining expert has reported very favorably upon several deposits in the Mozambique Company's possessions. The mineral wealth of South Africa is indeed magnificent, and British enterprise will find a wide field therein for a long time to come. Prospects are so far superior to those afforded in the history of any previous auriferous development in that the country's gold mines lend themselves to a business-like and extensive pursuit of the industry not hitherto possible. The element of speculation ought to have less to do with South African gold mining than it has had to do with the winning of the precious metal in any part of the world. So long as the purchaser of shares is sure that a sufficient capital is available for honest development work, it is hard to see where he can hope to find a better opportunity for a sound and remunerative speculation than in South Africa.

BUILDERS OF
"Sensible" Horse-Power Hoisting Whims.
(DAVIS PATENT.)

PRICES REDUCED.

The "Sensible" Hoist is the cheapest and beyond doubt the
best in the market. It is built entirely of iron and steel, mounted
on a heavy iron base plate, and is therefore very durable and
not affected by exposure to climate influences.

The hoist gear on the drum shaft is loose, and, on hoisting,
drives the drum through a friction clutch. This avoids the re-
quent accidents occurring with other whimes, occasioned by the
breaking of the gear teeth when throwing them out of gear. In
lowering, the drum is pressed by a powerful screw lever against
brake woods at the opposite end. Perfect means of adjustment
are provided for the friction clutch and brake blocks.

As the drum is entirely independent from the driving gears
the operations of hoisting, dumping bucket and lowering can be
performed with the horse in constant motion, a feature not pos-
sessed by any other horse hoist in the market, and one that
greatly increases the capacity of the machine by avoiding the
loss of time due to stopping and starting the horse.

It is very light and compact and very easily taken to pieces
for transportation by mules. The cost of erection is very small,
two men in half a day being able to put it in place ready for
work.

Weight of hoist, 1200 lbs. Total shipping weight, including
sweep, levers and sheaves, 1400 lbs.

Circulars giving Capacities and Prices furnished
on application.

Adamantine Shoes and Dies

Scientific Progress.

Possibilities and Impossibilities of Science.

Professor A. B. W. Kennedy, F. R. S., delivered a lecture in the Royal Institution, on "Possible and Impossible Economies in Energy Utilization," a subject which he described as of national interest, as economy in energy might mean wealth and prosperity to a nation, while waste in energy might mean diminished commerce and general depression. As an engineer he stood on the firm basis of the fact that nothing was impossible except perpetual motion and the transmutation of metals; and about the latter it was hardly safe to be sure, for Professor Dewar might shortly tell them that at a temperature of about 273 degrees everything was the same, the difference between gold and lead being only a matter of thermodynamic function. In essence, all the impossibilities he would have to mention were perpetual motions—attempts to get more out of something than was in it. He gave, as instances, the attempts to utilize the steam in an engine over and over again, and to make out of coal a fuel which had twice the value of the coal itself. A man who said he was going to produce 25 out of £1 would be laughed at. To the good folk who dabbled in physics and chemistry and patents, it was always possible to conceive that some new law, or force, or source of energy, or what not, would rise, Minerva-like, fully equipped for the use of the universe, and particularly for making their individual fortunes out of a casual suggestion or a random experiment. He thought it was not impossible to arrive at some understanding as to how far existing knowledge could be held to be final, and how far provisional. More than half the possibilities of economy were possibilities of improving up to the best work already done. If, for instance, the average working of steam boilers all over this country were brought up to the standard of the best working, about 30 per cent of our coal would be saved. He analyzed the working of electric-light plant, compressed-air plant and electric-tramway plant, as well as steam and gas engines, and said there was no very large possibility of saving in the generation of electricity, but there was an enormous possibility of economy in utilizing the current for light in the lamp itself. He also emphasized the importance of super-heating steam. To sum up, there seemed to be no very startling possibilities before us except in increasing the efficiency of electric lamps and bringing up gas engines to their theoretical maximum. In other respects, matters would develop more or less rapidly, but always less and less rapidly as they approached the limit of efficiency. There was no one point in which we had not some measurements enabling us to set bounds to the possibility of improvement, and thus to gauge the value of the pretensions made by each new method or invention as it appeared.—Electricity.

PROF. DEWAR gave the second of a series of lectures at the Royal Institution, London, recently on the atmosphere. His first point had reference to the presence of metallic particles in the air and the manner in which they were disseminated. There was a theory that they were caused by cosmic dust. In volcanic eruptions they had been carried to great elevations, especially in Krakatoa. Turning to the subject of pressure, he pointed out the value of mercury in this respect, remarked that air is 10,000 times lighter than mercury, and then conducted an interesting experiment to show that an air barometer is sensitive to atmospheric pressure to a millionth part of an inch. He then demonstrated that in the same way as they could measure atmospheric pressure they could measure gases, coal gas, for instance, being lighter than air and carbonic acid heavier. This brought him to the question of the effect upon air when it has been evaporated into it a substance such as water. On this point he had an interesting method of showing the difference between air saturated with water as compared with air in the lecture theater, the result being to establish the fact that air charged with aqueous vapor is lighter than dry air.

ALTERNATING CURRENT PHENOMENON. Mr. Maicillac, in *La Lum. Elec.*, describes the following experiment, which he believes confirms to some extent statements made by Mr. Tesla regarding the effect of surfaces: A small Geissler tube, 4 to 6 inches long, has one end connected to one pole of an ordinary Ruhmkorff coil, while the other end has the platinum wire filed off close to the glass, the second pole of the induction coil being disconnected and insulated; below the

free end of the tube is placed a porcelain dish insulated by a plate of ebonite placed on a large plate of glass; the end of the tube is then lowered until it touches the liquid; if then the finger of the hand is touched to the liquid the tube will glow; if, after the light is once established, the finger be withdrawn the light will diminish, but will still continue; if then, while thus disconnected from the water, the hand is brought near to the free end of the tube the luminosity will remain almost as intense and will have the same rapidity of vibration; if the end of the tube is then again lowered into the liquid the luminosity will continue. Numerous different liquids were tried with the same result. The experiment may be performed very easily and requires but an ordinary Ruhmkorff coil and a few small batteries. It is very important, however, that the spring of the vibrator is very thin and elastic, and that it vibrates like the wings of certain insects, like the dragon fly, for instance, rather than like the blows of a hammer. As this experiment requires only such apparatus as every physicist has, he suggests this as a simple way to show on a small scale some of the Tesla phenomena.

Glazing as a Science.

Glazing is being exploited as a science by Mr. Edward Atkinson, who, in a recent talk, told most interestingly of certain experiments he has conducted and experiences he has had in relation to the quantity, quality and usefulness of light as received through different sorts of glass.

At a meeting of the British Association, said Mr. Atkinson, an explanation was given of the Fresnel lens for transmitting light in one beam horizontally. Now, by reversion, a glass apparatus has been made to serve as a diffuser of light. You will be surprised to know that the amount of light that is absorbed by ribbed glass is ten per cent and by clear glass is eight per cent; that there is only two per cent difference in the obstruction of light between a double thick German clear and a fine ribbed plate of the same thickness.

Now, through plain glass you get no diffusion; your light falls directly on the floor, and the clear sunlight falls on your looms or frames, if you are at work in a factory, making dark shadows, while with the ribbed glasses you get a diffusion through the room without a glare. You need no window shades and you have no desk shadow. Then, in the practical use of light, you will get a vast deal more with that ribbed glass without window shades than you will with the clear glass with the window shades which you must have on a south side.

An inventor, continued Mr. Atkinson, worked on my theory of window glass. He has applied this idea to a conical glass, which is put under the arc light; with this he has done away with the glare and destroyed the shadow. You may have daylight from an arc light in your mills without the shadow and without the glare. The dispersion of light through the ribbed glass is relatively 64 per cent in horizontal planes to 0 per cent in plain glass.

SPONTANEOUS COMBUSTION OF ARSENIC.—Recently, powdered metallic arsenic which, in the process of powdering, had been moistened with water to prevent dusting, is recorded by E. Hirschsohn as capable of spontaneous combustion. A quantity of powdered arsenic in a double paper bag had been received late in the evening, and set aside over night in a basket containing other articles packed in straw and sawdust. The next morning, upon opening the store, the peculiar garlic-like odor attracted attention to the basket containing the powdered arsenic. An examination disclosed that the arsenic had agglutinated to a solid glowing mass; that the paper containers had been charred, and that a portion of the straw was scorched. A number of bottles in the basket had also burst, owing to the high heat, and upon the charred paper bag were sublimed some beautiful crystals of arsenious oxide. A fire, which probably would have been attributed to some other cause, was in this case averted.—Pharm. Ztschr. f. Russl., 1892, 612; Am. Jour. Pharm.

THE CONQUESTS OF MODERN SCIENCE. Surely I have established my thesis that dirt is only matter in a wrong place. Chemistry, like a thrifty housewife, economizes every scrap. The horseshoe nails dropped in the streets are carefully collected, and reappear as swords and guns. The main ingredient of the ink with which I now write was probably once the broken hoop of an old beer barrel. The chippings of the traveling tinker are mixed with the parings of horses' hoofs and the worst kinds of woolen rags, and these are worked up into an exquisite blue dye which graces the dress of courtly dames.

The dregs of port wine, carefully decanted by the toper, are taken in the morning as seidlitz powder to remove the effect of the debauch. The offal of the streets and the wastings of coal gas reappear carefully preserved in the lady's smelling bottle, or are used by her to flavor blanc-manges for her friends. All thrift of material is an imitation of the economy of nature, which allows no waste. Everything has its destined place in the process of the universe, in which there is not a blade of grass or even a microbe too much, if we possessed the knowledge to apply them to their fitting purposes.—North American Review.

Mechanical Progress.

Demand for Engineering Tests.

Dissatisfaction is expressed by engineers, by manufacturers of boilers, engines, motors and railway appliances and by fuel companies with the methods of making awards at the World's Fair, says *Iron Age*. It is understood that no sort of test is to be made of any engine, motor or fuel or mechanical device whatever. It is greatly to be deplored, these engineers say, that the exposition authorities have seen fit to neglect such an important matter. Here, they say, is an opportunity such as never before existed for the world to acquire a fund of information valuable beyond all computation to engineers and to manufacturers. Every type of engine, steam generator, gas and other motor; all methods for the transmission of power by compressed air, electricity, wire rope; all sorts of carrying machinery, and numberless other mechanical devices are here gathered together ready to have their comparative merits shown, and the opportunity is to be passed by. It is understood that no provision has been made for comprehensive scientific tests as suggested by the American Society of Mechanical Engineers. It is urged that not only practicing engineers but business men desiring to engage in some line of manufacturing could refer to the reports made and have an actual, unprejudiced account of the performance of any engine or machine in which they might be interested, instead of being forced to rely on the assertions of manufacturing agents.

This would not necessitate any competition, the engineers say. All tests of each class of exhibits could be made on the same line and the results published by the World's Fair authorities. They agree that even if Mr. Thatcher would carry out his single-judge idea and provide means of making tests it would be a big thing. It would be better for all concerned, they say, to have fewer judges and spend some of the money thus saved in making the tests.

As for the manufacturers who have exhibits at Jackson Park, they seem to have taken it so entirely as a matter of course that tests were to be made that most of them expressed great surprise when it was intimated to them that such was not the case. Had they known, many of them say, that no tests were to be made they would not have spent so much money in making exhibits. Some go still further and declare they would have made no exhibits at all. In brief, it would seem that all concerned are extremely anxious that tests be made.

In December, 1892, a committee appointed for the purpose by the American Society of Mechanical Engineers, at the request of the Committee on Awards of the World's Columbian Exposition, presented a report on methods for physical and mechanical tests of steam engines and other machines. After dwelling upon the great opportunities afforded by international expositions to keep pace with the developments of other nations in the various departments of science and art and for careful tests of the relative merits of the various products, manufactures, machines and methods developed under different conditions in various parts of the world, the committee recommended a most elaborate series of tests, going into great detail for the guidance of the National Commission. Although submitted in due form and in good season, it is said, this report was practically ignored by the Committee on Awards. Its suggestions have not been acted upon. Whatever merits the exhibits of engines, boilers and motors may possess will from present indications not be disclosed at the fair. All exhibits of this class will be there exclusively on appearances.

A NOVEL GRAIN DISCHARGER.—A novel and very interesting machine is now in use at the Millwall docks, London, for the discharge of cargoes of grain in bulk, the principle applied being the removal of the grain by the creation of a strong current of air. The machine is erected on a barge,

which is placed alongside the ship to be operated upon. To the machine is attached one end of each of six five-inch flexible pipes, the other end of which is carried into the hold or holds of the vessel and immersed a few inches in the grain. The engine is then started and the grain immediately flows at the rate of 100 tons an hour through the pipes into receivers, whence it falls by gravity into weighing machines, and then again by gravity into the craft sent by buyers to receive it. The machine in use has a power of 100 tons per hour, but the work done can be increased indefinitely by the addition of a corresponding engine power. The six pipes are worked together, but when necessary more or less of them can be shut off, and the rate of discharge is then reduced, but not in proportion to the number of pipes detached. With one pipe only in use this power exercised carries 38 tons an hour through it.—Transport.

The Production of Open-Hearth Steel.

The production of open-hearth steel ingots in the United States in 1892 was 669,889 gross tons, against 579,753 tons in 1891, and 513,232 tons in 1890. There was an increase of 90,136 tons, or over 15 per cent, in 1892 as compared with 1891. The production of 1892 was much the largest yet attained in this country. Our production of Bessemer steel ingots in 1892 was 4,168,435 gross tons, or more than six times as great as our production of open-hearth steel in the same year. Nevertheless our open-hearth steel industry has made steady progress in recent years.

Our statistics of the production of open-hearth steel in the United States include steel made in the open hearth by the basic process, which we have not undertaken to separately classify. Direct castings are counted as ingots.

The production of open-hearth steel in 1892 in New England, New York and New Jersey amounted to 38,131 gross tons; in Pennsylvania to 551,010 tons; in Ohio to 60,834 tons, and in the other Western, Pacific and Southern States to 19,914 tons.

The open-hearth steel made in 1892 was produced by 63 works, located in 12 States—New Hampshire, Massachusetts, New York, New Jersey, Pennsylvania, Alabama, Ohio, Indiana, Illinois, Michigan, Missouri and California. The total number of completed open-hearth steel works in the United States at the close of 1892 was 80, or 9 more than at the close of 1891.

The quantity of open-hearth steel rails produced in 1892 was only 3819 gross tons, nearly all being made in California.

We have just received the statistics of the production of open-hearth steel in Great Britain in 1892, published by the British Iron Trade Association. The production in the year mentioned was 1,418,830 gross tons, against 1,514,538 tons in 1891, and 1,564,200 tons in 1890. The production of Bessemer steel in Great Britain in 1892 was 1,500,810 gross tons, against 1,642,005 tons in 1891, and 2,014,843 tons in 1890.

In the United States the Bessemer steel industry has received far more attention than the manufacture of open-hearth steel, while in Great Britain the production of open-hearth steel in recent years has encroached rapidly upon that of Bessemer steel. The production of Bessemer steel in Great Britain in 1892 was less than that of open-hearth steel in either of the years 1890 or 1891.—The Bulletin.

THE HYDEPHONE, A NEW APPARATUS FOR NAVAL WARFARE.—Experiments are, at the present moment, being carried on in France with an apparatus by means of which it is claimed that even in the densest fog the approach of a hostile vessel can be indicated to the distance of one mile. The apparatus, which has been called Hydophone, will prove very useful for the firing of a torpedo immersed at the entrance of a harbor. It consists of two parts. The first part is immersed under water at a depth of from 8 to 15 fathoms. The other part is on shore at a distance of about 5 miles from the point of immersion. The first part is an iron bell, weighing 170 kg.; its surface representing an exceedingly sensitive, isolated floating body. This sensitiveness is so great that the bell receives the vibrations caused by the revolutions of the screw of a vessel at one mile distance. These vibrations are electrically transmitted to the part placed on the shore, and there operate an alarm bell.

A SOLDER FOR ALUMINIUM.—The solder is an alloy of aluminium and tin, suitable proportions being 45 parts tin to 11 parts aluminium. The metals are melted separately, poured together, and then cast into suitable strips or ingots. No flux is required.

**GILPIN COUNTY PERFECTION
CONCENTRATORS**

ARE OUR SPECIALTIES.

**THE BLASDEL CONCENTRATING BELT COMPANY.**We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.First, the flanges or edges of our belt stand at an acute
angle inclining toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for the
space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.**H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.****CRANE COMPANY,**

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old
experienced, first-class Agency. We have able and trustworthy Associates and Agents in Wash-
ington and the capital cities of the principal nations of the world. In connection with our edi-
torial, scientific and Patent Law Library, and record of original cases in our office, we have
other advantages far beyond those which can be offered home inventors by other agencies. The
information accumulated through long and careful practice before the Office, and the frequent
examination of Patents already granted, for the purpose of determining the patentability of
inventions brought before us, enables us often to give advice which will save inventors the
expense of applying for Patents upon inventions which are not new. Circulars of advice sent
free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St. S. F.

ESTABLISHED 1866.

Pacific Chemical Works.**HENRY G. HANKS,**Practical and Industrial Chemist, Assayer
and Geologist.

718 MONTGOMERY ST., - SAN FRANCISCO.

Will report on the condition and value of any mining property on
the Pacific Coast. Rare Chemicals made to order. Instructions given in
Assaying and Practical Chemistry.

Electricity.

Electrical Problems and Experiments.

Nikola Tesla, the eminent electrician, in a recent interview, said:

"The present methods of producing light are very wasteful. The electric light is a considerable advance over the gas burner, as far as efficiency is concerned; yet even the electric light, as at present produced, is very inefficient. Of the energy of coal we only get one-third per cent in light in an incandescent lamp; much more, however, in an arc lamp, because in that lamp we can reach much higher degrees of incandescence and because we have the advantage of an economical combination of carbon and oxygen."

"It is true that in recent years some notable improvements have been made in gas burners, and that, from a theoretical point of view, it is possible that a far more efficient burner than the ones at present in use may be produced."

"Probably the most important problem electricians are considering is the production of electricity by an efficient process from coal or other cheap substance; at least, most engineers have this subject in view. I think it is fully as important, and, in the end, perhaps even more important, to apply our skill in discovering how to transmit power from the waterfalls to any distance, for then we would be able to obtain energy without consuming any material, and our coal fields and forests would remain untouched, whereas the production of electricity from some material will involve the rapid consumption of that material."

"One of the problems which is of great importance, and the solution of which we are likely to witness in a few years, is the transmission of intelligence to any distance without connection. From present experimental evidence it can be quite safely concluded that an attempt to transmit intelligible sounds through the earth from here, for instance, to the European continent without any cable will succeed beyond a doubt. But it is a question whether such a method, which I have advocated for two years, would be available for all purposes, such, for instance, as the use to which the Commercial Cable is put."

"In that case it is questionable whether the scheme would be practicable. But one thing is certain, we will be able to transmit universal time all over the earth, and also be able to send in the same way very important short messages from centre to centre."

"Electricity is becoming more and more an important factor in our daily life, and more and more closely connected with our comfort. I think, after a considerable lapse of time, it will become practically necessary for our existence. For instance, there is the question of light. The advantages of the electric light are so great that even with the present wasteful methods we have been able to succeed in making practical use of it."

"But what will be our success when we shall be able to produce a hundred times as much light as we do at the present day? To do this is merely a question of time. Electric power is obtained by the use of dangerous, cumbersome and complicated appliances. But we have electric machines now which require no attention whatever, and which will in a few years supplant all other motors, simply because of their higher efficiency and ideal simplicity."

"Even now the cost is very great. Eventually we will be very likely to be able to heat our stoves, warm the water and do our cooking by electricity, and, in fact, to perform any services of this kind required for our domestic needs."

"It has been said that it will be impracticable to heat our houses by means of electricity on account of the great cost of coal; but, as I have said, we are now looking for other methods of getting electrical energy cheap. Even with the present methods, any rich man certainly prefers, instead of a stove in his room, to have it warmed by electricity. The method is expensive, but ideal."

"Electric energy can be applied to bicycles, carriages and all sorts of vehicles. It will certainly be applied to rowboats and will probably be so cheap that any man in ordinary circumstances can own a boat and propel it by this means. It would be a gloomy prospect, indeed, for the world if we did not think that this great power will be used to the advantage of the vast majority of the human race, and its benefits will not be confined merely to the wealthy."

"I am working on some other lines than those of which I have spoken, and if I succeed in my experiments they will be of great interest principally to scientific men. They

have also a practical bearing upon what newspapers sometimes call the 'burning questions of the age.' These experiments are quite apart from old notions and the lines which heretofore have taken up my attention. I cannot tell how soon I will complete these experiments."

"Most of my experiments heretofore have involved either rapidly alternating currents of high potential, or have reference to these electrical waves which are set up by alternating currents, and which, if very rapid, will not go through electric batteries at all, but will go through the best insulators. If they are less rapid, they will go through electrical conductors fairly well."

"Some years ago I demonstrated that a lampate filament could be made to glow from a current from a human hand. The light coming from the hand is produced by the agitation of the particles of molecules of the air. I charge my body with electricity, and from an apparatus which I have devised I can make the electricity vibrate at the rate of a million times a second. The molecules of the air are then violently agitated—so violently that they become luminous, and streams of light then came out from the hand."

"In the same manner I am able to take in the hand a bulb of glass filled with certain substances and make them spring into light. I make light come to an ordinary lamp in a similar way, simply by holding it in the hand."

"When I was in London I had the pleasure of performing one of these experiments privately before Lord Rayleigh. I shall never forget the eagerness and excitement with which that famous scientist saw the lamp light up. I can only say that the appreciation of such men amply repays me for the pains I take in working out such phenomena."

Loss Between the Coal and the Electric Light.

The following remarks were made by Mr. Stillwell at the recent electrical convention held at St. Louis, regarding the losses incurred in using electricity as a medium for light and power:

"I want to say a few words in regard to the saving being effected at an early or late step in the process of transforming the potential energy of coal into light or power for sale. It seems to me that we should bring out the fact that a great deal depends upon the relative strength of these steps. The central station man who is paying for energy in the form of coal and selling it in the form of light is losing various amounts at each step of the process, but up to the present time he is losing far more before it gets to the dynamo than he is after it leaves the dynamo. I have made a few figures to illustrate this: Suppose we have 1000-horse power potential in the coal which we are burning under our boilers. I think the best figures which steam engineers will claim for the proportion of that coal or energy which they will deliver in the form of mechanical power to the dynamos in a station that is continuously operating will be about ten per cent. Now, if we apply figures, obtained from records at the Kensington, Eng., station, we will find that under the variable load he loses about three per cent of that, and it is this amount of the energy, which is really a very large amount at that stage, which the scheme of Mr. Halpin (heat storage) proposes to economize. Of the seven per cent that at the Kensington station, we will assume, is delivered to the dynamos, I think it can be demonstrated that the dynamos, the distributing circuits, under a properly-arranged system, will deliver to the terminals or lamps about 8 per cent, or 5.6-10 per cent of the initial energy of our coal. We again suffer a relatively heavy loss because up to the present time our incandescent lamps give us but a small proportion of the energy they receive in the form of light. I estimate that out of the 1000-horse power that the central station man buys in the form of energy in coal, he may be able to sell 2.8-10 in the form of light. He has lost in the various steps about 930-horse power before he has reached the dynamo. In the electrical apparatus down to the lamp he loses."

THE old axiom that lightning does not strike the same place twice would seem to be falling into disrepute. On the farm of G. W. Exford, near Carthage, on the Antwerp road, stands, or rather stood, an elm tree which several years ago was twice struck by lightning and has since gradually died. During the storm of July 8th the old tree was again struck, breaking off the top and leveling the tree to the ground.—Ogdensburg Journal.

Useful Information.

How Wall Paper is Made.

The processes of color lithography and wall paper manufacture are in a great many ways identical, and are equally interesting. skilled artists are employed by the wall paper manufacturers to originate designs and novel effects, the latter-day cultivation of the public taste demanding the production of artistic and pleasing designs. A half-day spent in the inspection of a manufactory for wall paper is a profitable experience. One is apt to carry away spots of color deposited unawares upon one's garments, but that doesn't matter when one is on the scent of art and knowledge."

From the artist's room, where the designs are evolved, to the shipping department, where they are despatched, finished in compact bundles, upon their several journeys, the process of production is full of interest. The first stage is the designing in water colors by the artist of the pattern which is to be reproduced. Then, as in chromolithography, the pattern is traced and an estimate made of the number of colors that are used in the sketch. Say there are five, then five seasoned cedar rollers are prepared to receive the five portions of the sketch which contribute the five colors. The process by which these different portions of the sketch are placed upon the rollers is immensely curious. The designs stand from the surface of the rollers in high relief, and consist principally of thin hammered brass and felt."

Where solid blocks of color are required, that portion of the design is outlined with thin strips of brass which can be bent in any shape, these being pounded into the roller with a tiny hammer, and the spaces between the lines are filled in solid with strips of soft felt. When these surfaces are rolled with paint they print on the paper solid designs, which perhaps represent the petals of a flower or the green of a leaf, etc. The first prints of color in the sketch are the body colors. Next in order come the shadings, the embellishments, dots of gilding, etc., each of these being defined upon a separate roller. The work of outlining these designs is exceedingly difficult and laborious, the workmen following the portions of the design which are traced upon the rollers beforehand in order to be exact."

The work of outlining the designs on the rollers being completed, the first step is to print the background on the plain paper. The paper unwinds from large rolls weighing half a ton apiece, slowly passing under the moving machinery, up over rollers which carry it along to the brushes, which move rapidly back and forth across the paper as the latter passes along under them, and it emerges covered even with the required tint. This paint, by the way, is all mixed with water. Oil paint is not used at all; and the paint dries several shades lighter than it is in the liquid state. This fact has to be calculated upon in producing effects."

To go back to the paper which has just received its background; it passes from the brushes up over a bar, traveling away from the machine and stretching out in a long sweep to where a double endless chain, extending nearly 200 feet, the entire length of the building, traveling upon a sort of miniature elevated railway, moves perpetually around and around the little railway. In these chains are notches which run parallel to each other, and they catch up in their progress, as they pass the nearest point to the tinting machine, wooden rods which are placed in a rack close to the chains."

These rods catch the paper at regular lengths, bearing it up on to the little railway from which it hangs in long loops, and the procession of loops hanging from the rods, resting upon the notches in the endless chains, marches slowly down the long building, drying en route from the heat that emanates from a series of steam pipes which are laid along the floor under the railway. The heat grows more and more intense as the procession progresses, and by the time the journey is ended at the other end of the building all vestige of dampness has departed from the paper. The latter is rolled again as fast as it accumulates and deposited in compact bundles upon the floor, ready for the printing of the design."

The accomplishment of the latter process is done by means of a machine which prints several colors at once. This machine is circular in form, and has places for the adjustment of the cedar rollers, which contain upon their rounded surfaces the different portions of the design to be printed, which represent the different portions of the color in the design. Suppose, for instance, a single design of a spray of wild roses with

green leaves on a delicate blue background is to be printed. The background is washed on by means of the process described. To print the design say five rollers are used. first bears the primary pink of the roses and any other touches of pink that may occur in the design."

The next color is perhaps the shading of the pink, the darker portions of the petals, the next the green of the leaves, the next the yellow of the stamens of the flowers, and so on; the more intricate the pattern, the more colors it takes to print it, the more work to impress the pattern in its different portions upon the cedar rollers, and the more expensive it is to reproduce. Many of the patterns have finishing dots or lines of gold, which lend brilliancy to the effect. These are all defined in the same way on a separate roller."

After the paper has received the whole of the design, winding around the big wheel and passing under each cedar roller, receiving tints, shading and embellishment, it sweeps out over the bar as described before, being caught up in long loops by the sliding rods which move on the endless chains, and the long procession of loops moves in order slowly down the building. It is a queer sight. At the other end of the little railway the wooden rods drop off from the chain into a big box, and as they accumulate they are taken out and removed to the starting point, where they again set out of their slow journey across the building."

An automatic arrangement on the printing machine puts a little red mark on the paper at regular intervals of so many yards, I forget how many—the length of an ordinary roll of wall paper—and at the other end of the building is stationed a boy whose duty it is to roll the paper into the small rolls in which it is sold. As fast as the paper arrives from the drying journey, it is wound around a small rod and at each red dot a sort of knife cuts off the paper, the roll is adjusted again and the work of winding proceeds.—Boston Transcript.

How to Live a Century.

First, live as much as possible out of doors, never letting a day pass without spending at least three or four hours in the open air."

Second, keep all the powers of mind and body occupied in congenial work. The muscles should be developed and the mind kept active."

Third, avoid excesses of all kinds, whether of food, drink, or of whatever nature they may be. Be moderate in all things."

Fourth, never despair. Be cheerful at all times. Never give way to anger. Never let the trials of one day pass over to the next."

The period from fifty to seventy-five should not be passed in idleness or abandonment of all work. Here is where a great many men fall—they resign all care of interest in worldly affairs, and rest of body and mind begins. They throw up their business and retire to private life, which in too many cases proves to be a suicidal policy."

During the next period—the period from seventy-five to one hundred years, while the powers of life are at their lowest ebb—one cannot be too careful about catching cold. Bronchitis is a most prolific cause of death in the aged. During this last period rest should be in abundance."

Anybody who can follow these directions ought to live to be one hundred years old at least. There is always this comfort, however, if we cannot live up to our ideas all ways, we can at least try our best to do so, and the steady effort will be bringing us constantly nearer them.—Medical Age.

BICYCLES are machines by means of which muscular power can be used in locomotion to better advantage than in walking, and persons using their muscles in this way are, as the word velocipede expresses, swift-footed. Mechanicians estimate that six miles can be ridden on a bicycle with no greater expenditure of power than is required in walking one mile.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 60-horsepower Engine and 48-horsepower Boiler with Ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILLESBY, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Gold Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care MINING AND SCIENTIFIC PRESS, San Francisco.

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,

ALSO OREMOALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

65 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scori-
fiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these sup-
plies since the first discovery of mines on the
Pacific Coast, we feel confident from our experi-
ence we can well suit the demand for these
goods, both as to quality and price.

Agents of the Denver Fire Clay Co. and
for the Morgan Crucible Co., Battersea,
England. Also for E. G. Denniston's Silver
Plated Amalgam Plates. The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of silver guaranteed. Orders taken at his lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

JOHN TAYLOR & CO.

Books on Assaying.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes thereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less concise writers.
The want of such a work has long been felt. It
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assay; Examples of Dressing; The Melting in
Crucibles; Scoriification; Cupellation; Weighing the Bead;
Parting; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Dupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1889. Price \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

**Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.**

SECOND EDITION—JUST OUT.

Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion,
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhart's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel
and Cobalt; Oromium; Bismuth; Arsenic; Antimony; Sulphur;
Slate; Note.
One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.
Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

AROUND PLYMOUTH.—*Amador Ledger*, June 3: Mr. Ray, president of the Consolidated Osceola Mining Co., is up looking after the interests of the company and is stopping at the Forest. President Ray has made some radical changes in the working of the mine and I think now the work of developing will be pushed with more energy. They think from measurements that they now have the tunnel within 40 feet of the ledge, and Mr. Ray expresses himself as sanguine that they will have it rich when they get to it. The Bay State has the water down now to the top of the level and, there being three of them, all 100 feet long, which makes a vast body of water, the work of lowering the water is correspondingly slower than whilst confined to the shaft. However, the machinery is all working good and the management confidently expects that the water will soon begin to drain from the country ground and gradually lessen until the bottom is reached, when it will be no bother to handle the water. Experience has taught that these subterranean reservoirs will eventually drain themselves when they have capacity to dump their water. The Baldwin mine is fast getting the machinery in shape and in a short time expects to fire up. I understand workmen and mechanics have been engaged for work on the machinery for the New London plant and that work on the same will be commenced very soon. The prospects in the Pioneer, I understand, grow more flattering as they get farther along on the lead. Several parties have been looking at Mr. Vaughn's fine prospect on the extension of the Caucasian and it would not astonish me to hear of a sale any day, for any person wishing to invest in this kind of property not being satisfied with this prospect had better quit hunting for rich mines. The Osceola people left instructions to their foreman to commence work on the extension which they located north of the original mine; the croppings on this extension look well; a good many miners think it a good location and predict, when properly developed, a rich mine.

Butte.

FORBESTOWN.—*Cor. Grass Valley Telegraph*, June 3: The industry which furnishes the 500 inhabitants of this place employment is gold mining. Forbestown is one of the oldest mining towns in California. In its early days its rich gravel deposits were known the world over, but at the present time gravel mining is on the wane and much industry is being plied to develop the large quartz ledges which abound throughout the county, and many years ago were not thought of while in the process of extracting the precious metal from the gravel. But modern ideas, together with cheaper facilities and improved machinery, have wrought a change, and to-day the vast quartz ledges, although of low grade, are worked to a handsome profit. At present only two quartz mines are in active operation in this place—the Gold Bank, under the able management of Harry P. Stow, and the Shakespere, superintended by Mr. G. Price of Calaveras county. The Gold Bank mine, although only worked to the depth of 350 feet, is a magnificent property, ably managed, and contains all of the modern improvements and appliances in mining. The mill is of 40 stamps and was erected by Mr. Geo. Nihell of Nevada City. The mine and mill employ about 125 men, and a reduction works, employing 77 men, is also run in connection with the mine. Henry P. Stevens has erected a new residence, complete in all its appointments and will compare favorably with any mansion in northern California. The Shakespere mine employs about 50 men and runs a 10-stamp mill, but is building an additional 20 stamps to the works. The mine is also worked to about the depth of 350 feet. Mining experts are here looking into affairs and in all probability some mining enterprise may be inaugurated. A large sawmill is being built, and at the present outlook Forbestown has a bright future and is destined to be a town of considerable importance.

Napa.

QUICKSILVER STRIKE.—*Middletown Independent*, June 3: The quicksilver mining claim belonging to Howard Fraser, G. A. Sacy, J. B. Jamison and S. E. Shore, located in Oat Hill mining district, Napa county, has reached a stage of development that makes it more than a mere prospect. The owners have done considerable work. A tunnel has been run into the ore body a distance of 100 feet, 70 feet being in rich ore. At the back end of the tunnel a crosscut has been started and is now in eight feet, showing the same character of ore that was found in the tunnel. It is the intention of the company to run crosscuts in opposite directions to the tunnel to develop the extent of the ore body. Eighty feet below the 100-foot tunnel another tunnel has been started. If as good ore is found in this tunnel as exists in the tunnel above, it will show that the property is of great value. A road has recently been constructed to the mine and is connected with the new Oat Hill and Calistoga road. At present the company is constructing a foundation for retorts, which will shortly be placed in position. When this is accomplished it is believed the mine will be in a paying condition. The situation of the property is such as gives it decided advantages for cheap working, there being plenty of water and wood, with the necessary site for furnaces. Assays made from unselected ore showed 30 per cent in quicksilver. This property makes the best showing,

for the work done, of any discovery that has been made in recent years, and it is predicted that it will take its place among the large quicksilver-producing mines of the State within a short time.

Humboldt.

MR. HARPE'S COAL MINE.—*Blue Lake Advocate*, June 3: Mr. George Harpe passed through town Tuesday en route to his ranch on Mad river. Not all Mr. Harpe's Mad river really was comprehended in the Goodman prairie farm recently disposed of to Mr. Wheeler. He has land left, and, from indications, a large vein of coal on it. He has prospected his coal find very little as yet, but he proposes this season to dive down into the bowels of the earth sufficiently to discover the extent of the coal whose outcroppings have attracted so much attention. All the specimens look and burn like first-class coal.

Nevada.

TAKING OUT GRAVEL.—*Transcript*, June 1: An immense block of gravel has been cut out at the Odlin drift mine and will be hoisted to the surface and washed in a few days. The gravel is mixed as to quality, some of it prospecting very rich and some of it being only ordinary. It is expected that plenty of rich gravel will be found in the Odlin before long. Ten more men will be given employment next week.

VERY RICH ORE.—*Grass Valley Telegraph*, June 3: There was quite a ripple of excitement in town last night when it was learned that very rich ore was coming out of the South Idaho mine. A fine ledge exists in the shaft at the depth of 65 feet, and the stringers on each side that lead to the ledge are filled with as bright gold as you would care to see. A harley sack full of the ore was brought to town last evening, and hundreds of people viewed the ore. The owners of the South Idaho have been tenacious in their efforts and now it is evident that they will reap a rich reward for their long and faithful work. Almost the entire stock of the mine is owned in Grass Valley.

A PAORPAROUS DISTRICT.—*Grass Valley Union*, June 6: At no time have the mining prospects in Grass Valley district been better than they are at present. From all sides come reports of rich strikes, and the specimens daily shown on our streets would draw assessments from the pockets of the least enthusiastic stockholders. It is gratifying to know that in many cases fortune has smiled on comparatively poor men and that the hard work and patient waiting of years have been at length rewarded. These discoveries are ample and conclusive proof of what every resident here knows—that so far as mining is concerned the work of this district has been hardly begun and that here the placing of capital will amply and richly reward all who seek a safe and sure investment.

REWARD HOISTING WORKS.—*Nevada Transcript*, June 5: The foundation is about laid for the hoisting works building at the Reward mine, near the Rifle grounds. It is to be a large and thoroughly substantial structure and will contain heavy material capable of sinking to a great depth. The Miners' Foundry has the contract to erect the works and will push the same to completion as rapidly as possible. C. C. Weisenburger has charge of the carpenter work and is doing a good job.

WHAT IT WAS WORTH.—The gold bar from the Federal Loan mine, which Superintendent Vincent was about to bring to town the other day, but concluded not to and thus escaped having it stolen by the highwaymen who subsequently stopped him, was worth \$2700. Had the road agents secured the bar, they would doubtless have taken a trip to the World's Fair at Chicago.

TO BOND A MINE.—*Grass Valley Union*, June 2: W. W. Chamberlain was up from Smartsville yesterday on some mining business. He is trying to get a company to bond the old Forlorn Hope quartz mine at that place. The mine is owned by San Francisco parties and they want to get a company to bond the property and develop it. The mine has turned out a great deal of good rock in days gone by and is no doubt a good piece of property. Mr. Chamberlain left last evening for his home, but will be here again at an early date.

WASHINGTON MINING NOTES.—*Transcript*, June 2: Considerable mining is going on in the Washington district. At the Eagle Bird everything is running full blast, 45 or 50 men being employed. A gentleman from Oakland named Berriman has been sinking a shaft on the Lindsey Hill mine and met with encouraging prospects. There is talk of the Yuba Company bonding or buying the Lindsey mine, which is not far from the Yuba. The old Hathaway mine is being prospected and some very rich quartz has been taken out. The ledge is large, but as yet the pay streak is small. Work goes ahead at the Spanish mine without interruption. There is little change in this mine from one year's end to another. Parties are expected up from San Francisco in a week or so to start work on the Cole & Williamson mine, on Washington creek. The German mine has been closed down for some time and the owners are undecided as to what they will do with the property.

Shasta.

PROMISING LOCATIONS.—*Shasta Courier*, June 3: Wm. Harvey, of Flat Creek, owns a couple of promising locations in that camp. On one location he has run a tunnel in 140 feet, and finds the vein from 5 to 7 feet wide. He is at present working on another ledge which is about 14 inches wide and produces some very rich ore, but the rock is so hard that little progress is made. He has a young arrastre and can crush 100 pounds daily from this ledge, with very satisfactory results. The reported strike on Muletown mountain, mentioned last

week, was made on a claim located and owned by George Abernathy and Wm. Chynaweth. Abernathy discovered a prospect on the place some time ago and later a small pocket was taken out by George and Ed Boswell, who were working on it. Abernathy and Chynaweth are sanguine of the mine panning out very rich, as the pocket was taken from the middle of the ledge. It is located between Olney creek and O'Neal gulch, near Kellner's, and is the largest ledge in that section, being 30 feet wide. It has been located many times, but no great amount of actual work or development has been made on the property. Jim Loag, we believe, in early days did take out and work some of the quartz, which returned \$8 per ton, a good showing considering the primitive methods of milling quartz in those days. Work has been actively pushed for the past two or three weeks on W. P. Miller's mill, just below Middle creek. A good force of men are employed, and the mill will be entirely refitted with new machinery. The old works will be taken out and a 10-stamp battery and a bigger boiler will be put in. Miller intends to run the mill on rock from the Hartman and neighboring mines, and will also do custom work. He intends to use a new electric-cyanide process which, it is claimed, will successfully work the baser ores of this locality. The management of the Clark, or old Harrison mine, at Quartz Hill, intends to increase the battery in a short time. They are getting away with about 25 tons daily, and the mine is said to be turning out bullion in a way that greatly pleases everybody interested in it.

CALUMET.—*Redding Free Press*, June 3: Samuel Sandry, foreman of the Calumet mine, was in Redding yesterday. He informs us that he has sunk a two-compartment shaft down 55 feet, and has run a crosscut some 80 feet to tap two ledges. So far nothing special has developed, but he expects soon to run across good quartz.

Siskiyou.

THE MINING INTERESTS.—*Yreka Journal*, June 3: Siskiyou county is great in extent and great diversity of resources. The mining interests of the county are attracting the attention of mining men and other capitalists. The buried wealth of old Siskiyou is beginning to be appreciated. Millions of gold have been taken from our mines since the "days of '49." The gold heretofore has been gathered from the surface, and far and wide the golden checks have been gathered in. That which lay near the surface yielded readily to the pioneer miner. The gulches and channels have given up the precious metal to those who sought for it, but the ledges that supplied the gold that has heretofore been gathered up are still imbedded in our lofty hills and mountains, and await the active prospector who will discover the source of the treasure. Gold is found in the high mountains and far beneath the surface in the lowest valleys. Our river-beds are strewn with gold, and whenever the channel has been diverted from its course, the shining metal has been found. No mines have ever been worked extensively in this county. That is, no bonanzas have been developed, but the numerous small mines that have been and are being worked demonstrate conclusively that our mining interests are still unknown, and the prospects are of the most flattering kind. The mines of the county include placer and quartz. While the placer mines have been the principal source of our gold yield heretofore, the quartz ledges are now looked to as the permanent supply, and wherein the interest is centered. There are a number of mining districts in the county, and each embraces a distinct area of country. We shall endeavor to speak of each so far as we have been able to gather reliable information.

HUMBURG DISTRICT.—This district is on the south side of the Klamath river, 15 or 20 miles west of Yreka, and includes the region drained by Humburg creek and its tributaries. So far, no extensive ledges have been developed, but there are numerous small mines that show the most encouraging prospects, and are being opened as fast as means and labor will permit. There are four mills in this district that are crushing a quantity of quartz. We will here speak of a few of the claims. The Hunt mine on the middle fork of Humburg is down 140 feet, and has a fine, well-defined ledge in the bottom. They are working a number of men, and the mill is kept going night and day. The Hegler Bros., on the North Fork, have struck the ledge in their lower tunnel. The quartz ledge is three to four feet wide, and is richer than in any other part of the mine. They are running the mill to its full capacity. Phillips & Cartright have a splendid claim. They have gone down on the ledge 300 feet and have just made a crushing of 25 tons, which yielded \$48 per ton. These parties have been much bothered with water, but now have it drained and will push the work. They have a good supply of timber on hand, and will now take out a large quantity of quartz. Humphrey & Jesserman have a well-developed ledge three to four feet wide and of a high grade. This is a promising property, and, with a little more development, which will shortly be done, will attract attention. The Galloo mine, owned by Clark and Wheeler, is showing a fine prospect. Jasper & Co. have over 400 feet of tunnel, and the claim shows a well-defined ledge. There are numerous other claims in Humburg district, but this will suffice to show what is being done. The miners all wear a smile, which indicates that they are satisfied. A number of capitalists and mining men from the lower country are investigating these properties, and ere long we may see extensive operations in this region. The formations in this region are generally granite, porphyry and slate. The gold-bearing quartz is found in the slate. There is some placer mining in this section. Morrison & Lash have a good claim of this character which is yielding nicely.

COTTONWOOD DISTRICT.—This district, on the north side of the Klamath, near the railroad, contains some fine mines, quartz and hydraulic. There is a quartz mine in the district, near the Oregon line, known as the Spencer, which is yielding a large dividend. The owners have a steam stamp-mill in operation, which runs through about eight tons a day, making a profit of over \$100 each day. Gilson & Co., near the Klamath, are working the Blue Gravel on a large scale. This is probably one of the most extensive hydraulic claims in the district. Large operations are projected and in working order in the Klamath river. Claims are numerous throughout this district and the adjoining district of Hungry creek.

SALMON RIVER DISTRICT.—Far in the southwest of the county, beyond the Salmon mountains, is a great mining region, known as the Salmon River district. Owing to the lack of roads to this region there has not been as much development to the mines as otherwise would have been. A road will be completed to this section this summer, which will create a boom and open up the country. There are now some excellent properties giving fine returns. As an illustration of the mines of this country we note one particular claim. Charles Nicolet called at the office and spoke of his own interests. He has a quartz ledge that varies from one to three feet in width, and the average yield per ton is \$37. He grinds the ore with an arrastre which is run by water-power, eight months in the year, and grinds three tons per day. The ore is easily taken from the ledge, and at this rate it yields a very handsome profit. As before stated, the want of roads has prevented the bringing in of proper machinery, and has necessitated working the mines in a primitive manner.

QUARTZ VALLEY DISTRICT.—This district lies southwest of Scott valley, and, like all of our mining districts, includes quartz and hydraulic mines. The Allen quartz mine has a good mill and other machinery on it, and has been worked for a couple of years. A. G. Myres is now erecting a mill on a claim in that vicinity, and has a quantity of high-grade ore in sight. The Campbell placer mine, in this vicinity, is now being worked successfully on a large scale by an English company, and from what we can learn, it will pay a royal dividend. This district has a high hope for the future.

DEADWOOD DISTRICT.—Some excellent mines are in operation in this district, which includes the region beyond the Greenhorn mountains, 12 or 15 miles southwest of Yreka. H. Schroder has an extensive mine with mill and complete works, and is doing a large business. Several other quartz and placer mines are yielding their treasure in the surrounding country.

YREKA DISTRICT.—A large area in the vicinity of Yreka has from the earliest days of mining in California yielded a large amount of gold. Placer mining has been the principal interest in this district, but there are certainly some good quartz ledges in the adjoining mountains, which supplied the auriferous gravel. Less than two miles south of Yreka is the Greenhorn Blue Gravel mine on the land of A. Lee. The claim is operated by Raynes & Austin. Enough work has been done to justify them in making extensive improvements. The gravel is 100 feet below the surface, and requires considerable machinery in the way of pumps, hoisting works, etc., to operate it. They have been idle for the last week, waiting for a new pump, but we understand a large force of men will be put to work immediately and push the work vigorously. It is generally conceded that this is one of the finest properties in the country. Several quartz ledges are under development in this vicinity that show good prospects.

SCOTT RIVER DISTRICT.—Forty miles west of the county seat is the old and well-known Scott River mining district. A large quantity of gold has been taken from the gravel along and adjoining Scott river. It has been worked since the early days. The Scott River Hydraulic Mining Co. has a large amount of money invested in the way of ditches, pipe, etc., and will no doubt take out plenty of gold. There are other companies in the vicinity operating extensive claims. As in all the districts, there are many smaller claims near that are doing well, and for want of space and data we cannot mention the particulars. Farther down the Klamath river are Sciad and Happy Camp districts, where are many good hydraulic and placer mines that are yielding good returns. A number of excellent claims are also successfully operated on Indian creek, which is 10 or 12 miles to the west of Yreka.

Trinity.

SALE CONSUMMATED.—*Trinity Journal*, June 3: The sale of the Ward mine was consummated last Saturday and the new company, under the name of The LaGrange Hydraulic Mining Co., has begun the survey of the ditch from the mine to Rush creek. It will be nearly two months before the survey will be completed and a call for men made. Mr. Beaudry says he proposes to have lines enough surveyed to be able to select the most practicable one possible. A great deal of the work will probably be done by contract.

GOON CLEAN-UP.—Another good clean-up was made at the Hubbard mine last Wednesday. This property is paying well, and as the company has a large territory it will be a good property for many years to come.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Enterprise*, June 3: 1500 level—The drift started west from the end of the southwest drift, 75 feet above the sill floor, has been extended during the week 62 feet; total length 77 feet; continuing in a quartz formation which assays from \$2 to \$4 per ton. 1650 level—Have continued

making necessary repairs to the drifts on the sill floor of this level and to extract some ore in working west from the old stopes, on the third floor, operating through the upraise, No. 6, carried up from the main northwest drift; also from the old stopes in working north from this crosscut run west from the northwest drift. The south drift started at the end of the crosscut run east from a point 60 feet up in the upraise which was started from the drift run west from these north workings, 27 feet above the sill floor of this level, has been advanced 13 feet; total length, 131 feet. From the end of this south drift an east crosscut has been advanced 23 feet in porphyry and quartz showing some value. Have continued to extract some ore of average quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. Have extracted during the week from all parts of the mine 187 cars of ore about 185 tons, the average assay value of which per car sample was \$32.23 per ton.

OPHR.—1565 level.—The west crosscut started from the bottom of the winze, sunk 52 feet below the sill floor of this level, has been advanced 19 feet; total length, 141 feet; in a porphyry, clay and quartz formation of low assay value. Late Thursday night, at a point 90 feet from the winze, a strong flow of water broke through the sides and top of this crosscut, causing a suspension of work in the face of the crosscut. We have a donkey pump at work throwing the water up to the 1465 level. Have continued the work of making the necessary repairs in the shaft, being joint work with the Mexican Company.

MEXICAN.—On the 1565 level.—West crosscut No. 2 from the north drift from the east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 23 feet; total length, 232 feet, continuing in porphyry formation carrying clay separations and fine lines of quartz. Have continued the work of making the necessary repairs in the shaft, being joint work with the Ophir Company.

UTAH.—340 level.—West crosscut No. 3 from the north drift, from west crosscut No. 2, at a point 195 feet from its mouth, has been extended 15 feet; total length, 196 feet; continuing in porphyry, quartzite and clay formation with a strong flow of water running from the face.

SIERRA NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 10 feet, making the total length 370 feet; the face is in porphyry and streaks of quartz. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 18 feet, making the total distance west of the joint shaft 3228 feet; the face is in hard porphyry and small streaks of clay and quartz.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level, has been advanced the past week 18 feet, making the total distance west of the shaft 3228 feet; the face is in hard porphyry and small streaks of clay and quartz.

ANDES.—On 420 level, have finished stripping north drift from east crosscut No. 3 to the face of north drift. Have been easing timbers in main north drift at east crosscut No. 1.

GOULD & CURRY.—200 level.—West crosscut No. 5, started in northwest drift, 432 feet from main west drift, has been advanced 5 feet; total length, 493 feet; face in porphyry. Also did considerable repairing during the week. **Sutro tunnel level.**—We have been cutting out ground and timbering same for a ewich. Owing to repairs being made to the Hale & Norcross incline, the men employed on this level have been unable to go to work during the last few days. During the coming week, when these repairs are finished, work will be resumed in the east crosscut, which was run from the main north drift near the south line.

BEST & BELCHER.—200 level.—West crosscut No. 2, started in northwest drift, 230 feet from our south line, has been advanced 14 feet, passing through porphyry and quartz; total length, 130 feet. 900 level.—West crosscut No. 4, started in southwest drift 112 feet from west crosscut No. 3, has been extended 18 feet through hard porphyry, and work in the same discontinued; total length, 91 feet. Also did some repairing during the past week. **Sutro tunnel level.**—We have been cutting out ground and timbering the same for a switch. Owing to repairs being made to the Hale & Norcross incline, the men employed on this level have been unable to go to work during the last few days. During the coming week, when these repairs are finished, work will be resumed in the joint east crosscut, which was run from the main north drift near the Gould & Curry south line.

HALE & NORCROSS.—1800 level.—Have done but little work the past week on account of retimbering the main shaft at head of incline, which prevented the use of the incline and necessitated the stoppage of operations on the 1800 level pending the completion of this work. Will resume work on this level on Monday morning next. Main shaft.—Are retimbering at a point where main incline connects with the shaft.

POTOSI.—Have started a drift south 35 feet west of the main shaft on the 850 level, which is now out 24 feet; face is in porphyry and streaks of quartz which give low assays. The south raise, 80 feet south of Potosi winze, 930 level, is connected with the south end of the stope above. The south drift, 200 feet east of Potosi winze, 930 level, is out 17 feet; face shows four feet of ore that gives fair assays. The north drift, opposite the last named drift, is out 102 feet; face shows five feet of fair-grade ore. Near the face of this drift have started an upraise, which is up 12 feet on the slope; the top shows 3½ feet of good ore. The south stope

above the 1000 level is up 52 feet, and yielding fair-grade ore. The north raise, above the 1000 level is up 121 feet on the slope; top is in fair-grade ore. The west crosscut, 1000 level, 120 feet south of top of raise from the 1100 level, is out 65 feet; face is in porphyry. Extracted and sent to Nevada mill the past week 552 tons and 250 pounds of ore from the 550, 930, 1000 and 1150 levels. Milled during the week 582 tons. On hand at mill 90 tons and 1500 pounds. Average battery assays, \$22.23; average car sample assays, \$25.50. Shipped to the U. S. Mint, Carson, 403 pounds crude bullion.

CHOLLAR.—We are yet engaged in making repairs to the north drift, 850 level. The east crosscut near the south line, 930 level, is out 267 feet; face is in porphyry.

WARD SHAFT.—This repairs to the two hoisting compartments of the shaft are completed, and are now lining up the pump shaft.

BULLION.—The repairs to the two hoisting compartments of the Ward shaft are completed, and are now lining up the pump shaft.

EXCHERQUE.—The repairs to the two hoisting compartments of the Ward shaft are completed, and are now lining up the pump shaft.

ALPHA.—The repairs to the two hoisting compartments of the Ward shaft are completed, and are now lining up the pump shaft.

OCCIDENTAL.—The main south drift, 650 level, continues in ore of fair grade. We have started an upraise from this drift at a point 310 feet south of No. 1 winze. The top is in ore assaying \$23 per ton. No. 6 crosscut from north drift, 750 level, is in 56 feet, and has reached the east wall. No. 7 crosscut on the same level is in 21 feet; face is in quartz and porphyry. No. 3 crosscut from Zedig drift, Sutro tunnel level, has been extended 15 feet; face in quartz and porphyry.

KENTUCK.—We continue to extract from two to three tons of ore per day from the 160 level of the average value of \$30 per ton. On the 1100 level we are extending the south drift in fair-grade ore, and have opened the third floor above the track, making the upraise 21 feet. The joint east crosscut near the north line is in 30 feet; face in quartz and porphyry. Have commenced shipping ore to the Santiago mill.

CON. NEW YORK.—The south drift from the bottom of the winze below the 650 level is in a distance of 68 feet; the face is in fair-grade quartz. No work has been done in the west crosscut from the southwest drift, 800 level, during the past week, on account of repairing.

SILVER HILL.—No work has been done in the mine during the past week.

Pioche District.

THE YUBA MINE.—Pioche Record, June 1: Shipments of ore from this mine of the Pioche Con. Co. to Salt Lake continue regularly, and, besides several cars unreported, about 30 tons of first-grade ore lies in the bins. This ore sells in open market for about \$110 a ton and is of a very desirable character. The recent development in the 1225 level of the mine, east, has opened up so well during the past week that the mine may now be said to look better than at any time in the past, and shipping ore for a long time to come at the present rate is uncovered. The ore is principally steel galena and heavy carbonate. The best showing is in the ledge opened three weeks ago in the ten-foot north crosscut from the 1225 level and about 400 feet east of the shaft, where two faces of ore are exposed—one five and the other four feet in width, each assaying from 96 to 222 ounces silver to the ton and from 40 to 60 per cent lead. The drift on the thirteenth level run west to connect with the old Mazepashaft has reached a distance of 932 feet, and yesterday sinking was begun to connect with levels of the Mazepa mine. When this connection is made, an abundance of good air can be secured which is what is badly needed in the Yuba.

Island Mountain District.

PLACER MINES.—Elko Independent, June 3: Island Mountain mining district is situated in the northern part of this county, 75 miles north of Elko. This camp is strictly a gold country, and gives, under the present management, promise of being a great producer of the yellow metal. These mines were sold last December to a wealthy Colorado syndicate, now known as the "Island Mountain Mining, Milling, Land and Investment Company." It owns a number of placer claims and quartz ledges. Its purpose is to improve this property by establishing an entirely new water system. This will require 12 miles or more of ditch and the building of several reservoirs, which will be extensive, covering several thousand acres of ground, thereby storing all the flood waters, and enabling them to utilize thousands of inches of water that now cannot be handled. The reservoirs will supply about 4000 miner's inches daily during the entire season, and the ditch will give 400 feet pressure. The value of the placers is uniform and pays from grass roots to bedrock. The gravel averages about 9 feet; the gold is coarse and is worth \$19.45 per ounce. Judging from the character of the gold, these placers have evidently been fed from the quartz ledges. Nuggets upon bedrock are not uncommon. The company is now working night and day, running two giant and one ground sluice, thereby using every inch of water the present ditch will supply. There are employed about 20 white men who are moving large quantities of gravel and meet with very profitable results. The improvements will be commenced in July and completed before the snow falls, and he ready to husband all the water possible next spring.

Kennedy District.

RICH ORE FOR SHIPMENT.—Silver State, June 3: A. Fiege, one of the owners of the Gold Note

mine, is here with 15 tons of ore from that mine which is to be shipped to the Portland Smelting Works. The ore is very rich, samples which were made showing that it will work nearly \$200 per ton. Mr. Fiege says it is probable that a mill will be built in the district very soon. Mine-owners are not very anxious to ship ore on account of the heavy expens of transportation and reduction. A mill would make Kennedy one of the best gold camps on the coast.

Central District.

ANOTHER STRIKE.—Silver State, June 3: R. E. Staudinger, one of the former partners of the Blackbird mine, which was recently sold to Eastern parties, has made another rich strike of a gold-bearing ledge near the Blackbird. It is said to be very rich.

A GOLD MINE.—The Blackbird mine is turning out \$400 or \$500 a day of gold bullion.

DAKOTA.

THE COLD, HARD FACTS.—Deadwood Pioneer, June 2: Private advices from Rapid City would seem to indicate beyond a reasonable doubt, notwithstanding the positive assurances of General Manager Thorburn to the contrary, that the status of affairs at the chlorination works of the Black Hills Milling and Smelting Company, located in that city, is anything but satisfactory to either the owners or creditors. Without assuming at this time to either criticize or commend the merits of the plant as an institution for the recovery of mineral, we give the situation as gleaned from a very reliable source. The plant is idle and will probably not resume operations under its present management. The institution owes to its employees about \$10,000, and the men will not return to work until they are paid 40 per cent of this amount and assurance given that the balance will be forthcoming in a reasonable length of time. The men do not care particularly who manages the plant, so long as they are sure of their pay; but aside from these are other heavy creditors, sufficient to more than double the liability. These creditors, which include the Elkhorn railway, First National Bank, of Rapid, and several prominent business men of that city, have held a conference and are willing that the plant shall resume operations under new and experienced management, but insist that Mr. Thorburn is not the man to make it a success and unless he resigns they will press their claims to execution. These are the cold facts, given to us on what we have every reason to believe is reliable authority.

UTAH.

LEACHING WORKS.—Park Record, June 3: W. I. Salkeld, the famous millwright who constructs all the Ontario Company's mills and hoisting plants, arrived in the Park this week and on Wednesday, with the assistance of Snrveyor C. P. Brooks of Salt Lake, staked off the sight upon which the proposed new leaching plant for the Ontario Company will be constructed. The Record man interviewed Mr. Salkeld in relation to the proposed plant, but was informed that he knew absolutely nothing about the matter—didn't even know whether it would be built or not, and had no positive information to give out. All the same, the indications point strongly to the fact that the new plant will be constructed and that work will be commenced in the near future. A large bill of lumber has been ordered and is arriving daily, and several four-horse teams are kept busy hauling it to the site, where it is being unloaded and piled up. According to the stakes recently placed the structure will be 270 feet long by 80 feet wide, and the way lumber is arriving would indicate that the structure is to be quite that large in dimensions. Nothing definite as to size and construction may be known to-day, but the Record predicts that there will be within the next two weeks, if not before. In the meantime, it is quite encouraging to observe the present active signs favoring the construction of the new plant.

IT IS NOW FINISHED.—The Park City Sampling mill has been completed and is now in perfect working order. The main plant was completed and all the machinery given a thorough trial some days ago and found to be in first-class order. The plant could not be finished, however, until this week, owing to the fact that the elevators did not arrive when expected. They are now in place, have been tested, and the mills may be said to be one of the most complete and convenient plants in the West, and a credit to both Mr. Mackintosh and its builders, Messrs. Pape & Campbell. The structure is quite a large one, and contains the following compartments: Ore sheds, 40x150 feet; machinery room, 30x43; sampling room, 16x33; plate room, 16x16; machinery cellar, 20x24 and 16 feet in depth; and an engine and boiler room 28x33 feet, the latter being of brick with steel ceiling. The entire structure is really fireproof, as the roof and sides are covered with No. 24 steel roofing and siding, while the bin and wheeling floors are of heavy boiler iron. The dumping floor for teams is elevated, and is reached by a grade of 1.75 inches to the foot, and no trouble is experienced in drawing the heaviest loads up the incline. Bins have been set aside for all the regular shipping properties in the district, and the name of each mine is painted on the bin, which are numbered for various lots, so that no mistakes can be made. This floor is quite roomy, and will accommodate 16 four-horse teams at one time. The foundations for all the heavy machinery are in keeping with the balance of the plant and were put in to stay, and the vibrations experienced in the old mill are conspicuous by their absence. Throughout, the plant is perfect, and Mr. Mackintosh expresses himself as highly pleased with the substantial work performed by the contractors, Messrs. Pape & Campbell, who carried out the plans and ideas of the structure to the letter. The mill is capable of handling much more ore than the district now produces.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR WEEK ENDING MAY 30, 1893.

- 498,810.—CASKET HANDLE.—L. H. Bannister, Pasadena, Cal.
498,378.—GYMNASTIC APPARATUS.—T. Bessing, Los Angeles, Cal.
498,380.—HEATING APPLIANCE.—F. E. Browne, Los Angeles, Cal.
498,741.—GANO PLOW.—J. S. Butler, Tehama, Cal.
498,628.—SAW HANDLE.—M. M. Cope, Noyo, Cal.
498,245.—HAMMOCK.—C. A. DeLaney, Santa Barbara, Cal.
498,636.—EDUCATIONAL CABINET.—C. L. Ellis, S. F.
498,638.—TOOL FOR TURNING PIPES.—G. Englund, Seattle, Wash.
498,543.—GAS GOVERNOR.—A. Ford, Golden Gate, Cal.
498,714.—WATER-WHEEL REGULATOR.—C. Hagmair, S. F.
498,550.—ENCLOSURE STARTER.—Heintzelman & Noyes, Sacramento, Cal.
498,659.—SEWER CLEANING BRUSH.—S. E. Johnston, Selma, Cal.
498,363.—CHECK-RAIN DETACHER.—H. P. Kyes, Riverside, Cal.
498,355.—TROLLEY CATCHER.—C. A. Lord, S. F.
498,663.—SCENIC APPARATUS.—W. H. Lytle, Portland, Or.
498,669.—SCENIC APPARATUS.—W. H. Lytle, Portland, Or.
498,441.—TUBULAR BOILER.—E. L. Martin, Tulare, Cal.
498,688.—FURNACE WATER-BACK.—C. Nye, Newmar, Cal.
498,657.—ROAO CART.—G. J. Overhiser, San Diego, Cal.
498,726.—STRAPE GAO.—SPOOR.—C. W. Preston, S. F.
498,696.—SPRAYER.—A. G. Provin, Puyallup, Wash.
498,447.—CARBURATOR.—R. J. Rolison, S. F.
498,575.—CAR COUPLING.—F. M. Ryan, S. F.
498,449.—VENTILATOR.—C. H. A. Smith, Los Angeles, Cal.
498,318.—EXTENSION TABLE.—W. C. Steers, S. F.
498,400.—GAS GENERATOR, ETC.—T. A. Stombs, Los Angeles, Cal.
498,326.—CARB GRIPPER.—P. T. Taylor, S. F.
498,692.—NECKTIE FASTENER.—C. F. Ware, San Rafael, Cal.
498,597.—SEPARATOR.—F. H. Wheeler, Santa Barbara, Cal.
498,599.—SPRAY NOZZLE.—A. W. White, San Jose, Cal.
The following brief list by telegraph, for June 6, will appear more complete on receipt of mail advices:
California.—Hans G. Bshir, San Francisco, dynamometer; James H. Burrell and W. J. Doldge, Wright, machine for picking prunes or plums; Wilson Carey, Forest Hill, hand punch; Nathaniel M. P. Cose, Tustin, label-printing machine; Robert Franken, Pomona, hose-fastener; George Grisel, San Francisco, match-packing machine; Rudolf Hagen, San Francisco, faucet and faucet attachment; Benjamin Holt, Stockton, traveling thresher, also traction engine; Joseph B. Jordine, San Francisco, apparatus for treating or reducing bituminous substances; Robert J. Kennedy, Redlands, Ferdinand von Leach, Mirabel, water-wheel bucket; Lemuel S. Manning, Alhambra, car coupling; Charles C. Merrill, Riverside, joint.
Arizona.—Joseph L. Giroux, Jerome, furnace.
Washington.—Philip H. Dencor, Sprague, hose coupling; Frank Graham and I. E. Curtis, Easton, convertible stool; Charles Palmley, Seattle, dish-cleanser.
Nevada.—Alfred D. Godbe, Pioche, hobby horse.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

EDUCATIONAL CABINET.—Chas. L. Ellis, S. F. No. 493,636. Dated May 30, 1893. The invention relates to that class of educational apparatus in which a traveling strip of paper is confined within a casing and is viewed through a slight aperture. The objects of the invention are by a novel arrangement of the paper and the disposition of its supporting and guiding parts, to present a perfectly smooth, unwrinkled surface, to prevent the sagging of the paper and to hold it close up to the sight aperture, to confine the paper roll closely and guide it accurately in unrolling, and generally so to simplify the device so that its construction shall be practical and economical.

SAW-HANDLE.—Marshall M. Cope, Noyo, Mendocino Co. No. 498,626. Dated May 30, 1893. This is one of that class of saw-handles adapted to be readily fitted and adjusted to the saw and removed again when necessary. The invention consists in a stock having a forward-projecting flange provided with holding pins or lugs for engaging the holes in the saw-blade, a sliding clamp fitted to the stock and adapted to bear on the rear edge of saw and hold it tightly on the pins, and an oscillatory handle in the rear end of the stock provided or formed with a cam acting against the sliding clamp to force it to its work and to relieve it.

SPRAY-NOZZLE.—Archibald W. White, San Jose. No. 498,599. Dated May 30, 1893. The invention relates to spray nozzle of that class which are employed to discharge a spray upon trees, vines and plants for the purpose of destroying noxious insects or parasites, and it consists in the combination with the device of a strainer by which any solid matter may be held back and kept from passing into the nozzle, and also in a means for adjusting said strainer and in certain details of construction. The spray thrown by these nozzles should be exceedingly fine, and the very small holes required are easily stopped up, requiring stoppages for cleaning, but this invention obviates this.

SEWER-CLEANING BRUSH.—Septer E. Johnston, Selma, Fresno Co. No. 498,659. Dated May 30, 1893. This device is especially adapted for cleaning out vitrified stone and other sewer pipes. It consists of a peculiarly constructed brush having attachments at its ends, whereby it can be drawn backward and forward through the sewer to be cleaned. The brush is easily cleaned and the interior of the tube serves as a channel through which the water can flow constantly while the brushes are at work. By reason of the peculiar construction and the swivels at the ends of the rod the brush will be caused to rotate slowly as it is dragged through the pipe.

Market Reports.

The Markets.

SAN FRANCISCO, June 8, 1893.

Government Silver Purchases.

The Government purchases of silver for the month of May were as follows:

Date.	Price.	Ounces.
May 1.....	84.00 to 84.33	320,000
May 3.....	84.35 to 84.45	450,000
May 5.....	83.60 to 83.80	169,000
May 8.....	84.20 to 84.40	454,000
May 10.....	83.95 to 84.10	560,000
May 12.....	83.90 to 84.10	365,000
May 15.....	83.78 to 83.90	97,000
May 17.....	82.98 to 83.00	300,000
May 19.....	83.30 to 83.40	360,000
May 22.....	82.25 to 83.34	360,000
May 24.....	82.93 to 83.00	181,000
May 26.....	82.90 to 82.98	416,500
May 29.....	82.88 to —	100,000

Public awards.....4,132,500
Private purchases.....367,500

Total.....4,500,000

Purchases for account of June were begun on the 2d. Further awards were made to-day. The purchases will be continued on Mondays, Wednesdays and Fridays until the whole quota for the month has been secured.

Gold Coin Movements.

The gold coin movement of this port for the month of May may be stated as follows:

Coining in May.....	\$1,620,000
Paid in for duties.....	\$ 582,400
Exported.....	1,113,200

Total.....1,695,600

Loss to local circulation.....\$75,000

Extending the comparison to cover the first five months of the year, we have the following:

Coined Jan. 1 to May 31.....	\$10,180,000
Paid in for duties.....	\$3,017,500
Exported.....	6,708,300

Total.....9,725,800

Added to local circulation.....\$454,200

For the same time last year, the loss to local circulation was \$3,751,400.

Coinage at the San Francisco Mint.

The coinage at the San Francisco Mint for May compares as follows:

	1892.	1893.
Double Eagles.....	\$ 1,180,000	\$1,180,000
Eagles.....	440,000	440,000
Half Eagles.....	979,500	979,500
Standard Dollars.....	100,000	100,000
Quarter Dollars.....	60,000	60,000
Dimes.....	60,000	60,000

Total.....\$1,079,500

Total.....\$1,740,000

The coinage for the first eleven months of the fiscal year compares as follows:

	1891-92.	1892-93.
Double Eagles.....	\$24,565,000	\$18,220,000
Eagles.....	980,000	980,000
Half Eagles.....	1,079,500	1,252,500
Standard Dollars.....	770,000	700,000
Half Dollars.....	218,000	198,720
Quarter Dollars.....	676,020	179,000
Dimes.....	326,170	122,901

Total.....\$23,634,190

Total.....\$21,653,121

THE METALS.—Tin has developed considerable strength, after a long period of weakness. Lead shows no change. Copper is steady.

New York, June 1.—Following are the closing prices for the week:

	London.	N. Y.	Copper.	Lead.	Tin.
Thursday.....	37 1/2	82 1/2	10 85	3 92 1/2	19 00
Friday.....	37 1/2	82 1/2	10 80	3 92 1/2	19 00
Saturday.....	37 1/2	82 1/2	10 80	3 92 1/2	19 00
Monday.....	37 1/2	82 1/2	10 80	3 92 1/2	19 00
Tuesday.....	38	81 1/2	10 80	3 92 1/2	19 00
Wednesday.....	38 1/2	83 1/2	10 80	3 80	19 60

Fine Silver Prices.

Fine silver was quoted on the first of May at 37-1/2 in London and 83 1/2 in New York. The

price was a trifle higher on the following day, but afterwards receded. The lowest point was reached on the 17th, when the quotation was 37 1/2 in London, and on the preceding day 82 1/2 in New York. On the 31st of May, the price was 37-1/2 in London and 82 1/2 in New York. The extremes in both markets for the first five months of the year were as follows:

	—London—		—New York—	
	High.	Low.	High.	Low.
January.	38 9-16	38 2-18	84 c	82½c
February.	38 8-16	38 2-16	84½	83½
March.	38 6-16	37 9-16	88½	81½
April.	38 5-16	37 4-16	83½	82½
May.	38 9-16	37 8-16	82½	82½

In May, 1892, the extremes in London were 40 1/2 to 39-11-16, and for the first five months of that year 43-12-16 to 39d.

Mining Share Market.

Little of special interest has occurred this week in the mining share market.

The monthly statements of the financial condition of the mining companies, sworn to by presidents and secretaries, were filed at the proper time. The following companies report having cash on hand June 1, 1893: Andes, \$14,492.76; Alta, \$13,933; Alpha, Con., \$119.67; Best & Belcher, \$18,320; Bullion, \$15,716.43; Bodie Con., \$11,155.55; Belcher, \$10,651.91; Consolidated California & Virginia, \$91,993.51; Consolidated Imperial, \$2604.87; Crocker, \$323.47; Crown Point, \$1970.85; Challenge Con., \$3051.24; Chollar, \$3609.40; Caledonia, \$9166.68; Exchequer, \$3507.91; Gould & Curry, \$17,767.01; Hale & Norcross, \$897.16; Lady Washington, \$6800; Mexican, \$13,331.51; Mono, \$5781.93; Nevada Queen, \$834.24; Occidental Consolidated, \$914.42; Ophir, \$11,051.04; Peer, \$433; Peerless, \$915.74; Savage, \$12,727.03; Sierra Nevada, \$15,073.92; Seg Belcher, \$3448.53; Scorpion, \$1871.6; Silver Hill, \$341.96; Union Consolidated, \$16,383; Utah Consolidated, \$2360.54; and Weldon, \$502.99. Standard Con., \$42,001.95; Syndicate, \$16,571; North Commonweal, \$229.86; and Julia Con., \$1610.60. The following additional companies report having had an indebtedness June 1, 1893: Belle Isle, \$6309.86; Del Monte, \$24,547.75; Navajo, \$11,524.36; North Belle Isle, \$7401.39; and Silver King, \$3966.29.

The following mining companies report having had an indebtedness June 1, 1893: Bulwer Con., \$4,117.38; Confidence, \$606.90; Commonwealth, \$26,570.91; Consolidated New York, \$14.34; Grand Prize, \$741.60; Kentuck, \$429.36; Overman, \$19,273.41, with \$17,798.51 to be collected on the pending assessment; Pitoe, \$20,911.02.

In conversation with Col. Hayward, a reporter was told the Potosi mine continues to show steady and general improvement. The 930-foot level has turned out to be a much better level than the 1000. The large station for the upraise in the ore body in the north drift on the 930-foot level will soon be completed, and the raise, which will be of two compartments, will be carried up in the ore body. The development work in the mine has been slow, on account of a poor supply of air, but Col. Hayward said that they would remedy this ere long. Arrangements are being made to increase the bullion yield and thus reduce the indebtedness of the company, which is now about \$20,000.

The Mount Diablo mine has been shut down for an indefinite period. The company's mill at Soda Springs is now being cleaned up and will soon suspend operations.

For the month of May the mining and other corporations on and around the Comstock paid out \$101,171 for labor. That sum was \$5472.54 less than the amount paid out for April.

WHO PAY TOLL?

Mill Owners Who Don't

USE THE CELEBRATED

BRYAN ROLLER QUARTZ MILLS.

HOW?

BECAUSE it is the simplest Roller Mill made, therefore IT SAVES IN RUNNING EXPENSES.

BECAUSE it is the only Roller Mill made in which oil is prevented from dripping into the pulp (oil makes it impossible for the quicksilver to amalgamate with the gold), therefore IT SAVES THE GOLD FROM GOING INTO THE TAILINGS.

BECAUSE—well, there are too many ways of paying toll, and besides it would only weary you to read of them.

All who use the mill can testify to its merits. We want to sell you a mill, so write to us for testimonials and particulars, or to some of the users—it makes no difference.

SOME OF THE USERS:

THE CANDELARIA CONSOLIDATED MINING CO., San Dimas, Durango, Mexico.....	4 mills.
THE TABOR MINE AND MILLING CO., Bakers City, Oregon.....	4 mills.
ELKHORN MINING CO., Bakers City, Oregon.....	2 mills.
PHENIX MINING CO., Oroville, Cal.....	1 mill.
GOOD HOPE CONSOLIDATED MINING CO., San Diego, Cal.....	1 mill.

AND MANY MINES ALL OVER THE WORLD, whose addresses we will gladly send you on application.

SAN JACINTO ESTATE, LIMITED,
 Office of General Manager,
 P. O. Address, South Riverside, San Bernardino Co., Cal.
 CALIFORNIA, Dec. 18, 1891.

MESSRS. ADAMS & CARTER, 182 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.
 I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

For any information, or for pamphlets, or for circulars or testimonials, call on or address

THE JOHNSTON CONCENTRATOR.

Among the many devices and improvements of late years in Mining Appliances, considerable ingenuity has been shown in the development of a perfect Concentrator. More time and thought has been given to this machine than any other connected with Mining Machinery. The result has been one marked progression, and in the JOHNSTON CONCENTRATOR which we are now building, we claim to have the most satisfactory machine yet evolved from the many types previously in use.

The points of excellence are briefly as follows:

SIMPLICITY OF CONSTRUCTION,

GREAT DURABILITY, EASE OF OPERATION.

INCREASED PERCENTAGE OF SULPHURETS SAVED.

We might have gone into columns of explanation, but it is doubtful if you would be better convinced of its merits than by reading the following testimonial:

MR. GEORGE JOHNSTON, San Francisco:

DEAR SIR: After a careful examination and a close study of your Concentrator while in operation, I do not hesitate to pronounce it, in my judgment, to be the most superior machine in the market. Its durability and simplicity of construction are its first points and are essential ones. The rocker motion immediately settles the sulphurets to the canvas belt, which retains them with any amalgam that may pass the plates; it leaves the sulphurets very clean; retains all the fine sulphurets; and does the work of two Frues running by the side of it.

Mine Bell Signals.

The law passed by the last Legislature, known as the Voorhies Act, requires the use of a uniform system of mine bell signals in every mine in the State where any signals at all have to be used. The object of this law is to avoid confusion in signals, so that when miners go from one mine to another they will not have to learn a new local code. Some superintendents object to the new signal system as too complicated, but as the law requires it to be used, the objections amount to nothing. Section 3 of the law says: "Any person or company failing to carry out the provisions of this Act shall be responsible for all damages arising to or incurred by any person working in said mine during the time of such failure."

The foreman is compelled, under this law, to see that one printed sheet of these signals and rules for each level, and one for the engine-room, are attached to a board not less than 12 by 36 inches, and securely fasten the board up where the signals can be easily read at the places stated.

With the MINING AND SCIENTIFIC PRESS of last week we sent a supplement containing the signals and rules, printed in full legal size, and stated that copies on cloth could be procured at this office for 50 cents each. A number of orders have been received for these. Mining superintendents are reminded that the posting of these signals and rules is compulsory.

THE Alaska-Treadwell Gold Mining Company paid a bonus dividend of 37½c. per share on the 12th, the same amounting to \$75,000. This is equal to the one-hundredth part of the price paid by the United States Government for the whole territory of Alaska. The mine has been paying regular dividends for some time, and has the reputation of mining and milling its gold ore as cheap as any company in the United States. It is owned largely by California men and the mill, water-wheels, concentrators and all the machinery was designed and built in San Francisco. The officers and white miners are all California men. A good deal of the labor employed is "Siwash" or Indian. The mine is really a big quarry of low-grade gold ore. There is free water power and supplies are landed on Douglas Island for about the same rates of freight that the railroads charge now to Grassy Valley. This is an advantage

of ocean transportation. The mine is equipped with one of the largest milling plants in the United States.

CAPTAIN H. L. HOWISON, Commandant of the Mare Island Navy Yard, who was president of the Naval Board of Inspectors that conducted the final trial trip of the coast defense monitor Monterey, has received word from Washington that the report rendered by the board is highly satisfactory in every particular to the Department, and that the official announcement of the final acceptance by the Navy Department of the Monterey

The Jarecki Pipe Machine.

The pipe threading and cutting machine of this type are made in several forms and are very convenient tools. The dies are quick opening and adjustable. Each set of four pieces cuts two sizes of pipe, which is a great point in favor of the machine when new dies are required. After the pipe is threaded there is no hacking off the dies as in the ordinary manner. All that is necessary is to open the dies and run the die head back. If the pipe is to be cut off the dies will expand far enough to admit of the pipe

passing through them to the cutting-off knife. When the dies require sharpening they can be quickly removed and ground on any ordinary grindstone. The die head is also provided with an adjustable stop pin, which is very convenient when a large number of threads of the same size are to be cut. Ordinarily every time a thread is to be cut the dies must be carefully reset. With this adjustable stop the dies are first set to the size to be threaded, then the adjustable stop moved and secured, which will only allow the cam to move to the point required to thread the proper size without the necessity of carefully resetting for every thread that is to be cut. The pump insures a steady supply of oil to lubricate the dies and knife.

There are no loose bushings on the machine which when required cannot be found. There is on the back end of the spindle an adjustable self-centering chuck to center the pipe. There is also one on the die head to steady the pipe when being cut with the cutting-off knife. The gripping chuck is self-centering, too, and very powerful. The Parke & Lacy Company of this city are agents for these machines and others made by the Jarecki Manufacturing Company.

THE ship Elmbank, which came to this port with a cargo of 1000 tons of coal and 2400 tons of sulphur, had a fire break out in the sulphur after arrival here. The water from the engines did no good, and Prof. Price arranged barrels on deck in which carbonic acid gas was generated, which was run into the hold and the fire thus extinguished.

THE Oakland Board of Health has decided to ask the City Council to appropriate \$15,000 for a garbage crematory and \$8000 to purchase a site.

FRONT VIEW.

BACK VIEW.

THE JARECKI PIPE THREADING AND CUTTING MACHINE.

is but a matter of a few days. This is a subject of congratulation in view of the false statements made about the results of this trial. The board found no defect in the hull or fittings, except some few minor details. There was no defect in the machinery or boilers of any kind. We are very glad that this is so. The Union Iron Works of this city made a first-class job with this vessel, and deserves both the credit and the money. It seems strange that misrepresentations should have been made when the truth was bound to come out in the end.

MCCARTHY'S QUICKSILVER MINE on Cinnabar Hill has petered. After a month's practice as a miner Mr. McCarthy has become convinced that there is no fortune for him below the surface, and all the blue rock that has come up out of that thirty-foot shaft and forty-foot drift will be replaced. McCarthy's mine will become a part of San Francisco's history, but its owner will not be able to make even a well out of it, as the water supply gave out long ago.

Comment.

Any miner who works a hydraulic mine, large or small, without a license from the duly authorized Commission, is a very foolish man, as he is liable to severe penalties. The Caminetti Act was approved on March 1st and the penalty clause came into effect on May 1st. It is perfectly true that the Commission was not organized on that date and was not ready to issue licenses, so it was not the miner's fault. At the same time the law is very plain in providing that hydraulic mines shall not be worked without a license after May 1st. Therefore any one conducting his mine by the hydraulic method now is doing so in violation of the law. There may be an exception or two in the cases of those mines which are working by direct permission of the courts, or in those where the debris can not ultimately get into the streams; but, generally speaking, those hydraulic claims being worked on the drainage basins of the Sacramento and San Joaquin rivers are doing so in violation of the law. There has been plenty of warning and those who now violate the law will get no sympathy if they are punished, and deserve none. Hydraulic mining is now a legal, legitimate industry, under certain specified conditions, but may not be carried on in portions of this State without complying with those conditions. Miners who evade or defy the law will be apt to be punished, and their punishment is easier under the new law than before it was passed. All trouble can be avoided by asking for a license to mine and waiting until it is issued.

The California Debris Commission have received several petitions for license to mine by the hydraulic process, but as yet nothing has been done with them. The Commission, though organized, is not quite ready to make examinations of mines. Certain inquiries have been made and pending the answers from Washington no active steps will be taken. In a week or ten days more, however, all the preliminary details will have been arranged, and the Commission will go on with its work. In another column we print the revised rules of procedure before the Commission. Some slight changes have been made in those printed last week. Those miners who wish to be ready for the next season, should make the necessary petitions as soon as practicable, since, as has been stated in the PRESS, it takes several months to arrange matters and issue the license. While the Commission will not necessarily visit the mines in the order of their applications, those who ask first are, of course, apt to be served first. To reduce the traveling feature as much as possible, whoever visits the mines will examine as many as he can on each trip, so if there are several in one district they will all be visited at one time.

RIVERSIDE is shortly to have an electric railway system, as a corporation has been formed and a franchise asked for the construction of a line in the principal streets of the city. The capital stock of the corporation is \$250,000.

The Water and Electric Power Plant at Bodie.

In July of last year the Standard Mining Co., of Bodie, determined to install a water and electric power plant to furnish motive power for the stamp mill and do away with the use of steam in consequence of the excessive cost of wood at Bodie. This work has now been completed. An excellent water-power was found at Green creek, a mountain stream on the north slope of Castle Peak in the Sierra Nevada, forming one of the chief sources of the East Walker river, and arrangements were made with the owner, Mr. T. B. Hickey, granting the company perpetual right to its use for power purposes, under very favorable conditions. This stream carries 500 miner's inches of water at its lowest stage, which is more than enough for the mining company's purposes, and runs six or eight times that amount at the time of melting snows. An old ditch was cleared out and practically rebuilt for a length of nearly one mile, and a site selected for a power-house at 355 feet vertically below the lower end of the ditch. The work of clearing the ditch, building dam, head-gate, waste-weirs, flume and penstock, the power-house and of laying and anchoring the pipe was pushed during the months of August, September and October, and in November the water-wheels were put in place, so that the first of December saw the water-power planted completed and ready to run.

At the same time this was building, the pole-line was constructed following a straight line 12½ miles in length over the mountains from the mill to the power-house, the copper wire was strung thereon, and 14 miles of telephone line was built between the Bodie office and the power-house, but at a distance from the power line in order to avoid induction and consequent bad service of the telephones. The motor foundations were also put in at the mill, and a motor room (26 feet by 18 feet) built.

Lumber and other material from the dismantled Bulwer-Standard mill was used in construction of Green Creek, thereby greatly reducing the cost. The power-house (30 feet by 40 feet in size) was the former salt house, and the penstock, or pressure tank, was one of the water tanks at that mill, while the steel receiver at the lower end of the pipe was made at the mine from an unused steam-drum. The ditch is 4558 feet long and is connected with a penstock by a short piece of flume fitted with the usual screen, sand-box waste-weir and flushing-off gate.

The pipe leads into a steel receiver, 40 inches in diameter by 9 feet 8 inches long, from which four taper pipes lead the water under pressure of 350 feet vertical head on to as many 21-inch Pelton water wheels, each pipe being fitted with two nozzles, and each wheel capable of developing 62½ horse-power. The wheels run at 865 revolutions, and the wheel-shaft will be connected by a patent insulating coupling to the armature shaft of a Westinghouse, 120 kilowatt alternating dynamo, generating current at 3530 volts. A Doolittle governor is attached to the wheels, and a No. 2 Pelton motor has also been put in to run the "exciter," required for generating the initial current in the fields of the large machine.

The pole line from dynamo to motor is 67,752 feet long, or 12 46-100 miles. The poles are of round tamarack timber 21 feet long, 5 inches in diameter at the top, 25 feet poles being used through the town, and where the ground required it. They are spaced 100 feet apart, and fitted each with a 4-inch by 6-inch by 4 feet cross-arm boxed into the top of the pole, and fastened with one bolt and one lag screw. The wire is of No. 1 B. & S. gauge soft drawn bare copper, and is attached to a standard double petticoat deep-grooved glass insulators, carried on "Klein Patent" ¼ inch by 8 inch iron pins. The wire used is of large section, but the distance of transmission is just at the midway point where cost of converters about equals the difference in cost between a No. 1 and a No. 6 wire, hence it is better to use a higher potential and large wire and avoid the complicated and often troublesome converter. The loss of potential on the line is estimated at 15 per cent, and the current delivered to the motor will therefore be of 3000 volts tension. The motor is of 120 horse-power, and will be brought up to speed by a small motor of 3 to 4 horse-power, which is built on the same bedplate with the larger, and thrown out of circuit as soon as the latter is running at the proper speed, or in synchronism with the generator at the power-house.

Two transformers (ratio 30 to 1) of 100 incandescent lights capacity each will be used for lighting the mill and company's offices are Bodie. With good water-power available and wood costing \$10 per cord at the mill, giving a monthly fuel bill often exceeding \$2000, the economy of this electrical power plant is self-evident. A statement of the cost of this plant will be useful to other mining companies. Legal expenses and consulting electricians cost \$295; general expenses, \$139.35; ditch, \$1787; penstock, \$363.13; roads and bridges, \$203.25; pipe line, \$3490.30; power-house, \$807.04; water-wheels and found-

ations, \$2105.16; wire line from power-house to mill, \$3094.16; pins and insulators, \$291.69; wire, \$6968.40; telephone line, \$1069.92; motor room at mill, \$527.93; machinery for connecting motor to mill shafting, \$1263.32; watchman, \$180; total expenditures, \$22,584.63. The total cost per mile was \$840.63.

Sacramento and Hydraulic Mining.

At a meeting of the Executive Committee of the State Miners' Association, on Friday of last week, Mr. Ingram, a merchant of Sacramento, was present, as bearer of the following communication from wholesale merchants of Sacramento:

SACRAMENTO (Cal.), June 8, 1893.

Hon. J. H. Neff, President of the California Miners' Association, San Francisco—DEAR SIR: We are in receipt of your communication inviting us to be present at a meeting of the Miners' Association to be held June 9th. We beg to thank you for the courtesy shown, but owing to the limited time and absence from the city of many merchants interested, we are unable to have a full meeting to consider the very important subject of mining. However, the undersigned met last evening and discussed the subject in an informal way. From the information in our possession we understand that the present mining laws are satisfactory to the mining interests, and that mining can be safely resumed under the existing laws.

If such be the case, we are unanimously of the opinion that the laws should be given a thorough trial. We are also satisfied that the merchants of Sacramento generally are in sympathy with the miners and their interests, and want to see mining continued without molestation, provided the operations be so conducted that no injury to our rivers will result therefrom. Wishing your Association success, we are, respectfully yours,

WM. R. KNIGHTS & CO.,

O. MCCREARY & CO.

This communication has since aroused considerable discussion in the valley papers, especially as the statement was made by Mr. Ingram that the Chairman of the Board of Supervisors of Sacramento had told him that on August 1st the Board will cease to appropriate money for the Anti-Debris Association.

Mr. Morrison denies that Sacramento is to withdraw its support from the Anti-Debris Association, but thinks the Caminetti law goes into effect in August, and there will then be no occasion for further litigation if the miners abide by its terms. Chairman Morrison says: "If the bill proves what it promises, and the miners do their part, there will be no need of further fighting. We are not fighting the Caminetti bill—there are some miners who don't want to wait until that law goes into effect, and those miners we are going to help shut down. The expression of our Board, and of the entire Association, is that we shall abide by the Caminetti bill. Our county shall continue contributing to the Anti-Debris Association until that bill goes into effect, and the miners proceed accordingly and confine their debris from destroying our river."

Mr. Morrison evidently did not know that the new law has already gone into effect, hence the misunderstanding.

This whole matter was brought up because a few miners had ceased to buy goods in Sacramento for the reason that they thought the merchants there were contributing to an association inimical to the miners' interests. The Miners' Association had nothing whatever to do with this, nor is there any organized movement among the miners. The owners of certain mines, however, did decide to buy no more mine supplies in Sacramento.

In our opinion this matter has been made to seem more important than it really is. No one can blame Sacramento for trying to preserve the river and opposing all miners who will injure the stream by their mining operations. The idea prevails, however, that the Anti-Debris Association intends to obstruct miners on general principles and contest all the applications for license presented to the California Debris Commission, which is to carry out the provisions of the new law. For instance, the Colusa Sun in making suggestions to the valley people says: "The miners cannot move without the commissioners, but we are not bound to accept the conclusions of the commissioners." It angers the miners when they are attempting to comply with the law to find the Anti-Debris Association threatening to contest them just the same as if they were breaking the law. If the miners find the association is not going to do this they will change their minds. If they find, too, that the Sacramento merchants will not aid and support the few anti-debris fanatics who believe in these extreme measures, the whole matter will be amicably settled without further controversy.

EDWARD MORAN has sued the Waterloo Mining Company to recover \$50,000 damages for personal injuries caused by the caving in of a portion of the company's mine in San Bernardino county. Moran was an employe of the company and working in that portion of the mine where the cave occurred. He charges negligence on the part of the company in permitting the mine to be maintained in an unsafe and dangerous condition.

Working Magnetic Iron Sands.

There is a very large deposit of magnetic iron ore on the railroad between Watsonville and Santa Cruz, in Santa Cruz county, about one mile from deep water. There are 202 acres in the tract, and the iron can be shipped either by rail or vessel. Several companies have worked this deposit of black sand for the gold it contains, but thus far none of them have made a success of it. An English company tried working the stuff with the lead bath process, but that was a failure.

The deposit has lately come into the hands of J. E. Taylor, formerly connected with the Portland (Oregon) Amalgamator and Mining Co. He intends working the sand in a new way and has provided the machinery for doing this. The Ball-Norton magnetic separator is used for separating the magnetic iron from the rest of the sand. Mr. Taylor expects to work 1000 tons of the sand per day, and will separate 650 tons a day of the magnetic iron ore, and this he is trying to find a market for in this city.

There is about 20 feet of earth above this beach sand, so the deposit will be "drifted." It can be mined for 15 cents per ton, and Mr. Taylor says will average \$2.50 per ton in gold. The water supply is rather limited and more is to be brought in. The amalgamator which Mr. Taylor is to use is the Raber, which was patented last month by N. L. Raber of Corvallis, Or., and is owned by the Portland Amalgamator and Mining Company. It has been very successful with the fine gold of Snake river, Idaho, and with beach sands. He will use three machines each with a capacity of four tons an hour or 96 tons a day of this sand. The magnetic iron ore is removed by the separator before the sand is worked for the gold in the amalgamator.

The amalgamator has a series of plated steps, across each one of which is a removable mercury trough, and the sand, etc., falls or drops directly from each step into the quicksilver. Above each of these transverse mercury troughs is a feed machine which automatically feeds small quantities of some chemical substance which keeps the quicksilver clean and lively. Mr. Taylor thinks these machines will lose no gold at all. No power is required for them, though each machine requires six miners' inches of water.

Out on the ocean beach south of the Park another set of men, under "Arraste" Johnson began to work a black sand deposit this week. They, too, want to sell the magnetic iron which they separate. Another new amalgamator, one invented by Johnson, is to be used at this claim. They only expect to get \$1.50 a ton from their sand.

We mentioned recently that at Crescent City beach some smelting works were to be put up for smelting the magnetic iron to be separated in operation going on there.

There are several other places on the California coast line where black sand is being worked for the gold. This gold is very fine indeed, and, being mixed in with magnetic iron of almost the same specific gravity as the gold grains, is very difficult to save. However, if there can be found a market for the magnetic iron ore, the magnetic separators can first take out this iron, and the residue can be worked for the gold. But if they cannot sell the iron, the operation will not pay unless the sand is richer than most that is found.

In fact these sands are usually poorer in value than they seem. The gold is in very thin scales and ten cents worth in a pan looks as if it were a dollars worth. This has fooled a good many men. In some places, after storms, when the gold becomes concentrated on the beaches by the action of the waves the sands pay very well indeed. The deposits back from the beaches, however, have to be worked right along. In drifting the sand deposits the work is very different from working in gravel, because when the sand gets dry it sifts down through the lagging and fills the drift. They have to caulk the chinks with moss to keep the sand back. This kind of mining has not paid well at Gold Bluff, where there is a very extensive deposit.

As to the deposit below Aptos, Mr. Taylor is confident that he can obtain \$2.50 per ton in gold. The Ball-Norton separator which he uses has a capacity of 20 tons an hour. They charge an enormous royalty for the use of the machine, however, altogether too big for ordinary beach-sand mines to pay. If they expect these machines to be used extensively here, they will have to make a material reduction in their royalty charges. There are several other forms of magnetic separators, all of which have been described in the MINING AND SCIENTIFIC PRESS by Thos. Edison and John Birkinbine, who have been making extensive experiments with such machines.

The iron from these sands is of very fine quality. As about all the iron we use here now is imported, it would seem as if some means could be adopted to utilize this magnetic iron, of which there is an abundant supply. The Santa Cruz mine alone would furnish more than our total

consumption. The trouble is probably lack of fuel, unless petroleum could be utilized. Works were put up at Saucelito some years ago to smelt this magnetic iron with liquid fuel, but they were not successful. Still, more is now known as to methods of burning the fuel, and it is to be hoped that experiment will show it can now be utilized in connection with the magnetic iron sands of our beaches.

Coast Industrial Notes.

FRESNO has voted \$75,000 bonds to build a high school. The offices of the southern division of the Santa Fe railroad, heretofore located in San Bernardino, are being removed to Los Angeles, to take quarters in the new depot recently erected in that city.

THE Oakland, Alameda and Piedmont Railway Company has received a number of new cars and placed them on its Alameda system. The company has made a new time schedule, and hereafter ten-minute trips between Oakland and Alameda will be in order.

COLFAX voted against the proposition to issue \$3000 in bonds for a schoolhouse, but the citizens have asked the School Trustees to call a special election for the purpose of issuing bonds in the sum of \$10,000 for buying the ground and putting up a school building.

THE new opposition freight steamer between this city and Oakland is going with the passenger business more than was expected and is to issue a commutation ticket for \$1, good for thirty rides. Single fares are now 15 cents. The boat has as much freight as it can carry.

THE Supervisors of Kern county have voted to submit to the people the question of issuing \$230,000 in bonds—\$50,000 for a hall of records, \$15,000 for a high school at Bakersfield, \$15,000 for a county hospital, \$30,000 for bridges and the balance for roads.

CHARLES H. ELLIOTT of Calico has filed a claim for 1,000,000 inches of the water of the Mohave river, to furnish water for the mines at Calico and Alvord, which is to be diverted by a dam across the river and carried by a canal to a natural storage reservoir, a dry lake ten miles from the mines. It is also expected to irrigate a large tract of the land.

THE Cudahy packing plant began slaughtering hogs in Los Angeles last week, when 200 hogs were slaughtered the first day. The works have a capacity of 500 hogs a day. They offer 7½ cents a pound for hogs on the hoof, and the supply is unable to meet the demand. Nor will it be, for there are no hogs in the country.—*Anaheim Gazette.*

THE first of the fourteen large passenger engines ordered by the Southern Pacific for mountain work arrived at Sacramento Wednesday. The new locomotive will be used in the Sierra Nevada and Tehachapi. They carry much more steam than the ordinary engine and have large and heavy driving wheels, which will enable them to pull longer and heavier trains over the grades than the engines now in use.

OF coal we received at this port last week from the coast mines 7398 tons; from foreign ports, 15,790 tons. The shipments recently from our northern collieries have been very light. Coal freights are low enough, as ship-owners claim that dividends are not dreamt of at going rates, and no great advance is expected in price, so that there cannot be much profit on coast coal products in the near future if the present conditions to them are unfavorable.

ACCORDING to statistics the wine merchants of San Francisco made last year about 2,000,000 gallons of dry wine, the wine-growers who market their own product made about 1,500,000 gallons, and the producers who sell their cellars to the wholesale wine merchants of San Francisco about 7,000,000 gallons, or two-thirds of the entire product. Mr. Herman Bendel suggests a combination of the producers which will put their wine into the hands of a Board of Directors who shall handle this wine so that better prices may be obtained by its growers.

ARRANGEMENTS were completed at Yuba City on the 13th inst. for the right of way to construct a canal as a cut-off at the mouth of the Yuba river. This cut-off, as accepted by the government on the recommendation of engineers, is to be 2400 feet long and 400 feet wide, with levees on each side. It will turn the current of the Yuba river into the Feather river at a point some distance below the present mouth of the Yuba, the object being to relieve the river during high water and make a more direct channel. The government will build the canal and work is expected to begin soon.

A PROPOSITION or scheme is on foot to sink a well across the river from Redding, Shasta county, in what is known as "Stinking" canyon, where 'tis said are many good indications of petroleum and gas. A year or so ago there was considerable excitement over the prospect of petroleum being found in that locality, and many locations were made. There was then talk of sinking a well, but it ended in talk; nothing was done and no money expended. Now it appears, however, that there are those who are willing to show their faith by their works, and who will put up a reasonable amount of coin for experimental purposes.

THE steamer Keweenaw, which sailed the other day for Panama, took among other things 503,000 pounds of California borax, which is destined to New York. In the cargo was also 18,000 pounds of antimony. The Willie Rosenfeld, now on the way to this port from Nanaimo, has 3800 tons; the Commodore has 3100 tons and the Kennebec 3500 tons. These are big cargoes. The mines of the Vancouver Company are now turning out 2300 tons daily, and can do better than that if pressed. The sinking of another shaft, which is among the possibilities of the future, will enable an output of 5000 tons daily.

THE Harbor Commissioners last week held an executive session to consider and examine preparations for making

piles used in the State docks teredo-proof. Chairman Bassett, who lately returned from a three-weeks' tour of inspection of all the principal wharves from here south to San Diego, presented a report containing much data. Some of the preparations will be given a trial in the bay. Commissioner Oole insisted upon a reduction in price in the future on all piles coated with paraffine or prepared with creosote; also that the length of piles be measured by a State employee and inspected before accepted.

ALASKA and British Columbia salmon have almost entirely supplanted the Columbia river pack in the foreign markets, and practically the entire pack of the Columbia goes East, where the demand more than keeps pace with the supply. This year Columbia river canners are figuring on a short pack, but it is too early to place great confidence in present estimates. Up to date the pack is behind that of 1892, chiefly on account of the destruction of the traps, a fact hardly to be regretted, as the loss has been in steelheads and other inferior salmon, and so, while the smaller, the average of the pack is much superior to that of 1892.

WORK on the ferry pier of the California and Nevada Railroad is progressing surely if not very rapidly. Already 1400 feet of piling has been driven from the Alameda shore near the Judson Iron Works. Shiploads of lumber will soon arrive and then the work of capping will soon be commenced, the completion of which will greatly facilitate the pile-driving portion of the labor of construction. The wharf will be run out to deep water and will be between two and three miles long. The ferry will tap the electric railway systems of north Oakland and cars of these lines will be run upon the pier to connect with the ferry boats, as well as the trains of the California and Nevada Railroad.

UP on the South Yuba river, about a mile above New York Flat, lie the deposits which may some day make Nevada county famous for its marble. There are four deposits, three of them quite extensive, and they comprise three distinct varieties of marble. There is a large deposit of a blue mottled stone called "dove" marble; black marble of fine quality; a considerable of the ordinary gray marble. This stone takes a very high polish, and that it is durable is shown by samples which have been cut out for twenty years and are still in prime condition. The owners of these valuable deposits are W. H. Kalenberger, N. O. Harmon, J. C. and A. L. Martens and L. W. Hutchins. They fully appreciate the value of their quarries, and this year intend to build a road from their ground down to the old Sailor Flat road, and will put their stone upon the market.

THE San Bernardino City Trustees have entered into a lease for a term of twenty years, by which they obtain from John L. Campbell the use of 100 inches of water for the annual rental of \$4950, with the privilege of buying the right for \$52,000.

Some three years ago the city erected water-works, obtaining the water from artesian wells. Owing to the large number of wells being placed at a point below, the wells of the city diminished in flow, so that costly pumping works had to be erected. Within the last few weeks even the pumping works failed to draw sufficient water for city purposes. The City Trustees propose in the near future to erect an electric light plant for lighting the city, and as the water just obtained by the lease has 100 feet fall before reaching the city reservoir, it will give ample power to light the entire city. The question of voting bonds for the purchase of this water will probably be submitted at an early day.

Mr. Hammond Goes to Africa.

Mr. John Hays Hammond, the well-known mining engineer, has recently returned from a business trip to London. Mr. Hammond has been connected in a professional capacity with many large mining enterprises on this coast, and has for some time been manager of the Bunker Hill and Sullivan mines of Cœur d'Alene, Idaho. He has been a contributor to the reports of the State Mining Bureau of articles of great practical value to miners and millmen. Mr. Hammond is about to leave California for some months and will go to South Africa on professional business. The *South African Mining Journal* has the following to say concerning Mr. Hammond:

"The firm of Messrs. Barnato Bros. may certainly be congratulated upon its choice of Mr. Hays Hammond as its technical adviser and consulting engineer, and it is probable that the high professional reputation which for many years he has deservedly enjoyed will go far to promote public confidence in the future of the companies with which he will be connected. While studying at Friburg it was generally predicted that he would eventually become one of the brightest ornaments of the mining profession, nor has his subsequent career in any way belied his early promise.

"On leaving the University he decided to thoroughly acquaint himself with the details of practical mining work in all its branches, and before practicing his profession served for several years in the mines with this object. At a later date he proceeded to America and soon attained a brilliant reputation, his fame now extending through all the various States of the Union. His attention has recently been chiefly directed to the famous gold mines in the Grass Valley district, California, of which he has acted for many years past as consulting engineer.

"His comprehensive paper upon 'Gold Milling,' reproduced in South Africa in the columns of the *Mining and Metallurgical Review*, will doubtless be remembered as a valuable contribution to the literature of the subject, and it is to be hoped that his investigations upon the Witwatersrand, with regard to this and other similar subjects upon which he is admittedly a high authority, will lead to many useful improvements being effected in the local conditions of mining and milling."

Refractory Metals in the Electric Furnace.

The name of Henri Moissan has figured very prominently in the scientific world during the last few days, and not without reason, the distinguished young French savant has lately made a series of experiments and discoveries whose interest is only equalled by the rapidity with which they have been successively placed before the public through the medium of the celebrated Paris Academie des Sciences. Mons. Moissan read a paper according to which he claims, by means of the electrical furnace capable of generating the extraordinary high temperature of 3000° Cent. that he lately invented, to be able to manufacture the diamond; on February 13th he contributed one memorandum upon a Canyon Diablo diamoodiferous meteorite, and another upon the presence of graphite, carbonado, and microscopic diamonds in the blue earth of Cape Colony; while on February 30th he utilized the furnace mentioned for the purpose of obtaining within ten minutes an ingot of the rare metal uranium weighing 250 grammes. Upon this occasion he pointed out that he had ascertained that a combination of this metal with carbon ignites spontaneously in the atmosphere, yielding a white light; and, by way of practical illustration, he, much to the alarm of his select audience, slyly shook a bottle containing a preparation of this class, with the result that a slight explosion followed. When the tumult engendered by this episode had subsided and the members had resumed their seats, Mons. Moissan exhibited ingots of chrome and manganese prepared in a few minutes in the way the uranium had been, whereas the ordinary reduction processes, he observed, absorb a comparatively long time. All things considered, the French scientist believes that the use of higher temperatures, which can be developed by a dynamo-electric machine actuated by natural water-power, will become an important feature of the art of metallurgy.

Iron gives the following further particulars of Mons. Moissan's process for the ready preparation of large quantities of the more refractory metals by means of the electric furnace. The electric furnace is simply a small furnace constructed of lime, so arranged that it can be intensely heated by a very powerful electric arc. A quantity of magnesia, which Mons. Moissan finds to be perfectly stable even at this high temperature, is first placed in the cavity of the furnace, and upon this is placed the crucible of retort-carbon containing a mixture of powdered carbon and the metallic oxide to be reduced. When the metal is volatile a current of hydrogen is passed through the furnace, and the vaporized metal is condensed in a comparatively cool receiver. In this manner Mons. Moissan has succeeded in rapidly preparing considerable quantities of the metals of the alkaline earths, calcium, strontium, and barium. If the metal is not sensibly volatile it is left in the crucible after the reduction in the form of an ingot. The rare metal uranium and the metals manganese and chromium belong to this category, and their preparation forms the subject of two recent communications by Mons. Moissan.

Metallic uranium was prepared with great difficulty, and only in small quantities by Peligot, by reducing the oxide with an alkali metal. At ordinary procurable temperatures the various oxides of uranium are practically irreducible by carbon. This no longer obtains, however, at the extremely high temperature of a very powerful electric arc. The nitrate of uranium is first calcined in a porcelain crucible, whereby a reddish-colored mixture of the sesquioxide and of green oxide U_2O_3 is obtained. This mixed oxide is then well ground with a very slight excess of powdered carbon, and the whole tightly packed in the crucible of retort-carbon, which is afterward placed in position in the time-furnace. Upon submitting the mixture in the crucible to the action of the arc produced by a current of 450 amperes, the reduction is completely effected in a few minutes.

The ingot of uranium thus produced exhibits a brilliant fracture and great bardness. It possesses the peculiar property of sending forth a shower of incandescent sparks when struck against a piece of porcelain, or when fragments of it are shaken about in a glass flask, reminding one of the combustion of particles of freshly reduced iron when allowed to fall through the air. The yield of the metal is very considerable; thus in one experiment of twelve minutes' duration an ingot weighing over 200 grammes was produced. The metal is not quite free from carbon, the amount of the latter depending upon the excess used. Mons. Moissan is now (*Nature* says) engaged in perfecting a ready mode of refining it.

In order to prepare metallic manganese the protoxide is mixed with carbon in the case of uranium, and the mixture submitted to the arc produced by a current of 300 amperes. The reduction is completely effected in five or six minutes, an ingot of 120 grammes being readily obtained. The comparatively weaker arc derived from a current of only 100 amperes gives the same yield in 10-15 minutes. Any large excess of carbon is to be avoided as carbides of manganese are then produced. If an excess of the oxide is employed the metallic manganese is almost pure, and may be preserved unchanged in open vessels. The carbides, however, are rapidly attacked by the moisture of the atmosphere, and if thrown into water evolve a gaseous mixture of hydrogen and various hydrocarbons.

Chromium has always been found hitherto to be much more difficult to reduce than manganese, but complete reduction occurs in 8 to 10 minutes in the electric furnace, employing a mixture of the sesquioxide and carbon and a current of 350 amperes, the yield being an ingot of 100 grammes. A current of 30 amperes, however, is sufficient to produce ten grammes of the metal in half hour's time. Moreover, it is possible to refine the somewhat impure (from carbide) metal by a simple repetition of the process in presence of a fresh quantity of sesquioxide. The pure chromium thus obtained is completely transformed into the volatile chloride when heated in a stream of chloride. The reduction in the electric arc succeeds equally well with

crude chrome iron ore, on alloy of iron and chromium may very readily be converted into chromate by projecting it into fused nitrate of potash or soda and subsequent extraction with water.

Pennsylvania's Bituminous Coal Regions.

The total production of the bituminous coal regions of Pennsylvania during 1882, according to the reports of inspectors was 46,018,247 tons. The 1st district comprises parts of Allegheny, Washington, Westmoreland and Fayette counties and the whole of Greene county. Henry Louttit, the inspector of this district, reports that there were 24 fatal accidents, an increase of 4 over the previous year. The number of non-fatal accidents reported to the inspector was 67; number of days worked 10,560, and 9393 persons were employed.

The 2nd district comprising parts of Allegheny and Westmoreland counties, has 85 mines which employ 12,009 persons. The number of tons of coal mined for each fatal accident was 320,760, and for each non-fatal accident 195,598.

The 3rd district comprises parts of Indiana, Westmoreland and Jefferson counties and the whole of Armstrong, Butler, Clarion, Lawrence and Mercer counties. There were 2 fatal accidents during the year and 26 non-fatal ones.

The 4th district comprises McKean, Potter, Tioga, Bradford, Sullivan, Lycoming, Clinton, Cameron and Elk counties and a portion of Jefferson county. James N. Patterson, the inspector, reports that the general condition of the mines throughout the district is much improved.

In the 5th district, composed of part of Somerset and Fayette counties, there were 23 fatal accidents and 60 non-fatal accidents. The number of tons of coal produced per life lost was 320,004; number of persons employed per life lost, 280; number of persons employed per non-fatal accident, 107. The 6th district comprises the whole of Blair and Cambria counties and portions of Clearfield, Indiana, Jefferson, Westmoreland and Somerset counties. The number of fatal accidents was 14, an increase of 1 over the previous year. In the 7th district, comprising parts of Allegheny, Washington, and Westmoreland counties, the most of the mines that shipped their product by river transportation were operated but a few months during the year, while some of the railroad mines could not work to their full capacity for want of transportation facilities. The number of fatal accidents and serious personal injuries, inspector Black says, are on the increase in this region, which fact is due to the very large number of foreigners now employed in the mines. The number of fatal accidents during the year was 28, an increase of 8 over the number for the previous year. The number of non fatal accidents was 56, but the inspector adds that it should be taken into consideration that there was a large increase in the production. The quantity of coal produced per life lost was 235,918 tons. In the 8th district, comprising Bedford, Centre, Huntingdon, and a part of Clearfield county, 12 fatalities occurred, and 53 non-fatal accidents.

Canadian Mineral Production.

The Geological Survey Department of Canada has prepared statistics of the mineral productions of the Dominion for each year from 1886 to 1892, which, although showing on the whole a steady increase during the whole period, record a falling off in the case of most minerals last year. The production of copper shows an increase from \$354,000 in 1886 to \$1,160,740 in 1891, but it fell to \$925,589 in 1892. Gold started with \$1,330,482 in 1886 and the output has declined year by year, until in 1892 it amounted to \$900,483. The silver production in 1886 was \$209,090, and steadily increased till 1890, when it was \$402,662, then declined to \$264,510 in 1892. Iron ore to the value of \$126,982 was produced in 1886 and has slowly increased with some fluctuations to \$142,005 in 1891; in 1892 it went up to \$254,206. Nickel statistics are given only for the last three years. The figures are \$933,282, \$2,775,976 and \$3,513,339, a very gratifying increase. The coal production shows an increase. In 1886 the value of the output was \$5,017,225; in 1891 it had gone up to \$8,144,247, but it fell last year to \$7,181,610. In mica the output in 1886 was \$29,008 and it has steadily increased to \$100,923 in 1892. The phosphate production, on the contrary, is decreasing. In 1886 it was \$804,638 worth; in 1891 \$241,603; in 1892 \$157,424. The total output of metallic ores in 1886 was \$2,021,548; 1890, \$3,570,685; in 1891, \$5,551,195; in 1892 \$5,807,049.

The non metallic ore production was \$8,096,719 in 1886; \$14,359,174 in 1891, and \$13,334,267 in 1892, the largest increase being in coal.

DRY WASHING FOR GOLD.—N. G. Hock, a mining expert from Denver, has just returned from the Altar district in Sonora, stopped over in Tombstone on his way home. He gives the *Prospector* some valuable information concerning what he says is the richest district under the sun. There is but one company operating there at present, a New York syndicate. They have 60 dry washers operated by 120 Indians whom they pay 75 cents a day. Their returns average \$1800 per week. The diggings are 60x80 miles in extent and as dry, hot and as barren as the Colorado desert. The nearest water is twenty miles distant and is packed on burros for domestic use. The gold was very coarse. Mr. Hock has several pieces which he was allowed to take from a washer that are worth from \$5 to \$20 each.

He states that many chunks are found mixed with quartz, that are as large as hen's eggs. He saw one piece which weighed ninety-six ounces after the quartz was cleaned from it which was purchased for a trifle from an Indian. One man cleans up the machines every night. He is the only American in the place. The gold is all sold to the merchants around the camp who take their chances in getting it out of the country without losing their lives.—Tombstone Prospector.

Shut-Down at Candelaria.

TO THE EDITOR:—The Mt. Diablo mine of Candelaria suspended operations on the 1st of this month, throwing out of employment about one hundred men at mine and mill. Owing to the steady decline of silver, the mine managers of Candelaria, about a year and a half ago, decided to either discontinue the working of these properties or reduce the wages 50 cents per man.

The proposition was placed before the employees of the Holmes Mining Co. Limited of London and the Mt. Diablo, the two principal mines in Esmeralda county. The men were told that when silver should again advance, the wages would be placed at the old standard. The proposition was instantly rejected by the miners, and both companies shut down.

One year ago the Mt. Diablo Company resumed work on both mine and mill and was run steadily up to the present time.

This county is prolific in her resources, and is rich in minerals, silver predominating; but there is also copper, lead, manganese, sulphur, etc., which can be worked. Owing, however, to the steady depreciation of silver, other industries suffer. It affects not only the miners and millmen, but the ranchers and the miscellaneous people who derive benefit from general mining operations. This country will suffer from Reno, Nev., down to Keeler, Cal., a length of 293 miles. If it were possible for the voting population of the United States to elect as its chief executive a financier instead of some one who looks at things from a Wall-street point of view, it would be better for all concerned. If I were an artist, I would paint a picture and exhibit it at Chicago in the mining department of the World's Fair, where it would attract attention and lead to inquiry. The subject would be "A lone Nevada prospector or miner is appointed to plead in terse English before her ladyship of Justice, whose eyes are bandaged."

Sodaville, Esmeralda Co., Nev., June 10, 1893. REX.

A Gold-Mining Center.

The recent mineral developments at both the east and west end of the valley mean much for Phoenix and the entire valley. Each day's report of the outlook in Superstition mountains has been more glowing than that of the day before, and people were at a loss only to know how much of them were true. Parties who have come down from the mountains say all the reports are true, that the only question is as to the extent of the ore, which they believe to be sufficient to make the largest gold camp in the United States. Further development is necessary to assure this, but the development is going on rapidly, the excitement is becoming more intense and all signs which precede great camps are prevalent.

At the other end of the valley, at the base of the Eagle Tail mountains, there is reason to believe that the greatest deposit of marvelously rich ore in existence has been discovered. It will require no very great amount of development to show this, as it is said that nearly five acres of it lie exposed. Reliable assays show it to contain gold in quantities ranging from \$200 to \$1500, and besides to contain a percentage of copper enough in itself to insure fabulous fortunes.

It is believed that these claims will prove to be the richest in the world, and there is no reason to disbelieve it, except that it appears to be phenomenal and without precedent.—Arizona Republican.

PROSPECTORS AND EASTERN CAPITALISTS.—Every prospect that looks like it might make a mine don't develop into one. It takes capital to develop a prospect into a mine. A man's labor is capital. Why all this nonsense written about Eastern capitalists being bitten in mines? If they put money into a developed mine they can measure its value the same as corn in a crib. If they won't take the pains to find out what they purchase they are not business men. If they purchase a prospect they have no guarantee that they will get their money back, yet on the other hand they may reap a rich harvest by the expenditure of a little money. The man who has the real risk is the one who seeks amid recesses of the mountains for the metals. He risks his life and if he finds nothing his time is gone for naught. He may locate good-looking prospects and spend years opening them up, with his limited means, only to find that there is no pay in it. Eastern people don't put money in mines, only for the expected gain, and if they lose occasionally it is no more than the prospector and real miner does. Is it not a fact that they win oftener than they lose; that millions taken from the western hills finds its way into the pockets of Eastern men?—Mohave County Miner.

C. R. McCLELLAN has been awarded the contract for building the entire line of the Donner and Tahoe Railroad. The length of the road is about ten miles and is to be completed by the first of July. The contract is a big one, including as it does the entire work of grading, filling in cuts and the making ready of a roadbed for a complete railroad. Work will be carried on along the entire length of the line. The ties and rails will be placed in position, beginning at the outer end of the line, as fast as the grading is done; so that by the time the last shovel-full of dirt has been thrown the road will be almost ready for use. By the end of July train loads of logs will be rolling into Truckee, and a new era in lumbering will have been inaugurated.

J. W. DUNLAP and J. W. Woodside, of Modesto, have filed an application with the Board of Supervisors for a franchise for an electric road. If granted a similar franchise will be asked from Tuolumne county. It is proposed to run the road from the San Joaquin river through Modesto and Oakdale to Sonora, a distance of sixty miles. Large quarries of marble and slate will be opened up to the market. The power will be furnished by the Stanislaus river, near Knight's Ferry.

Proceedings Before the California Debris Commission.

In the *Press* of last week we published the rules of procedure formulated by the newly organized California Debris Commission. Some slight changes have since been made by the Commission and we append a copy as revised and corrected. These instructions may be changed at any time as the experience of the Commission dictates:

SAN FRANCISCO, June 8th, 1893.

The California Debris Commission, appointed under the Act of Congress approved March 1, 1893, publishes for the information of all concerned sections 9, 10, 11 and 12 of the law which governs in the matter of presentation of petition and proceedings thereafter:

Sec. 9. That the individual proprietor or proprietors, or in case of a corporation its manager or agent appointed for that purpose, owning mining ground in the territory in the State of California mentioned in section three hereof, which it is desired to work by the hydraulic process, must file with said commission a verified petition, setting forth such facts as will comply with law and rules prescribed by said commission.

Sec. 10. That said petition shall be accompanied by an instrument duly executed and acknowledged, as required by the law of the said State, whereby the owner or owners of such mine or mines surrender to the United States the right and privileges to regulate by law, as provided in this act, or any law that may hereafter be enacted, or by such rules and regulations as may be prescribed by virtue thereof, the manner and method in which the debris resulting from the working of said mine or mines shall be restrained, and what amount shall be produced therefrom; it being understood that the surrender aforesaid shall not be construed as in any way affecting the right of such owner or owners to operate said mine or mines by any other process or method now in use in said State: *Provided*, That they shall not interfere with the navigability of the aforesaid rivers.

Sec. 11. That the owners of several mining claims situated so as to require a common dumping ground or dam or other restraining works for the debris issuing therefrom in one or more sites may file a joint petition setting forth such facts in addition to the requirements of section nine hereof; and where the owner of a hydraulic mine or owners of several such mines have and use common dumping sites for impounding debris or as settling reservoirs, which sites are located below the mine of an applicant not entitled to use same, such fact shall also be stated in said petition. Thereupon the same proceeding shall be had as provided for herein.

Sec. 12. A notice specifying briefly the contents of said petition and fixing a time previous to which all proofs are to be submitted shall be published by said commission in some newspaper or newspapers of general circulation in the communities interested in the matter set forth therein. If published in a daily paper, such publication shall continue for at least ten days; if in a weekly paper, in at least three issues of the same. Pending publication thereof said commission, or a committee thereof, shall examine the mine and premises described in such petition. On or before the time so fixed all parties interested, either as petitioners or contestants, whether miners or agriculturists, may file affidavits, plans and maps in support of their respective claims. Further hearings, upon notice to all parties of record, may be granted by the commission when necessary.

The Commission also publishes the following suggestions, instructions and information for present guidance of those concerned. These instructions are subject to such modification as experience may suggest:

The petition must, in addition to fulfillment of the requirements of the law, contain, or be accompanied by, a full description covering the following points and by such maps as may be required for illustration of the question, namely:

The name, location and extent of the mining ground; the route of travel thereto; the river which the drainage of the mine reaches and the names of the tributaries which it follows; the height of the bank to be mined; the character of the gravel; the source of the water supply; the length, fall and dimensions of the ditch; the length of the mining season; the number of inches of water proposed to be used and under what pressure; the daily duration of mining proposed, whether for 24 or fewer hours; the fall of the sluice in 12 feet; dimensions of sluice and the amount of gravel to be handled in an hour; the character of restraining barriers existing or proposed; a description of the site for impounding detritus; its area and capacity; position and character proposed for the barrier.

Brevity and clearness are to be studied in these descriptions.

The above-stated information may be sufficient to enable the Commission, in some cases, to dispense with maps, but in all cases of importance maps of the mining ground and of the reservoir sites will probably be necessary, and in all cases will probably expedite the action of the Commission. The Commission prefers, for expedition, but does not at present insist, that each case should be presented by a mining or civil engineer capable of giving necessary information.

It will expedite matters if all the miners in one particular locality will prepare and present their petitions as near as possible at the same time, in order that the mine may all be examined during one visit of the Commission.

In cases of a joint petition contemplated in Section 11, there should be a separate statement from each individual mine as to its proposed output, amount of water, etc., the same as provided for a single petition.

All maps, plans, petitions or writings of any description on file in the office shall be open for examination by any interested party.

On a day following the date fixed in the advertisement, provided in Sec. 12, the Commission or a committee thereof will attend in its office to meet the petitioners and contestants, for the purpose of gaining by inquiry such explanation as may be necessary for a full understanding of the case.

The Commission does not invite oral addresses and prefers that all questions submitted for its consideration be presented in writing.

The office of the Commission is for the present established in room 89, Flood Building, San Francisco.

All communications should be addressed to Major W. H. Heuer, Corps of Engineers, room 89, Flood Building.

Interest.

TO THE EDITOR:—If I should build a system of political economy, I should class all legitimate payments of money as *wages of service*. Gifts, whether forced or voluntary, are not payments and need not be considered. Fines are the wages of the service rendered by the community in protecting the delinquent from punishment at the hands of the injured. Wages would be divided into direct and indirect, and the various subdivisions would readily fall into their appropriate places. The guiding idea would be that such inventions as business, money, capital, rent, interest, profit, insurance, property, etc., were made for men and not men for them, as the Nazarene said of the Sabbath, and those figments would not be exalted and personified as gods or demi-gods before whose imaginary claims the rights of men would sink into insignificance, and before whose spurious altars men must bow down and worship. I may write more on this matter at some future time.

But I must not prolong this letter, else I shall be voted as great a bore as a political economist. The matter is simple enough, if one will but be content to plod along on solid ground rather than seek to tread the clouds, and I wonder that so many gentlemen of learning and talent have labored so long and hard on their several failures to solve such "an easy one." But I suppose it must be because they are so great. The eagle, soaring in the bright sunshine, would stoop in vain on the tiny mosquito which the little bat can catch with ease in the darkest night; the humble, creeping tortoise nibbles the tender grass-blade, while the stately giraffe browses on tree-tops. "We never see clearly the ground we stand on," wrote a great author, and the taller we are, the more extended our horizon, the more easily we overlook the modest flower which we vainly seek in the distant view. But let us advance on the enemy!

Interest is money. Money (or service) is justly demanded only in return for service (or money) rendered; therefore, interest is justly demanded only for service rendered, and hence, if interest is just, it must be shown that the receiver has rendered service to him who pays it.*

Does the lender of money render the borrower a service in addition to that represented by the money lent, and if so, what is that service?

Let us take a concrete example: A man finds himself "a little short" on Saturday after banking hours, and he wants to go to the Sunday picnic. He pays a visit to our Uncle Harris and hands to that accommodating person his gold watch, which will be much safer in our uncle's possession than in his own pocket on a crowded ferry-boat. Our avuncular relative, after inspecting the bauble and scrutinizing the applicant, for the good man must be cautious in these matters, hands out a double eagle, which is quite enough for one to "blow in" on a Sunday picnic, and a check or ticket which will insure the return of the watch if presented, accompanied by \$21, on or before the expiration of a month from date. The one dollar extra is for interest. Why should our uncle demand it? Doubtless he takes care of the watch, but he would otherwise have to take care of his double eagle, which would be much the same.

But our uncle might use his money; he might lend it to some one else, or he might go to the Sunday picnic himself. Can we expect him to forego those advantages to accommodate that man for nothing? Certainly not. He cannot get even by using the watch, because he does not know at what moment the man may call for it; he must have it ready for delivery whenever it may suit the man to take it "out of soak." This is the argument of self-denial, and self-denial for the convenience of another is service rendered to that other. But suppose he does not need to use the money, nor care to go to the picnic, and has more watches than he can use; and admit that, if he takes care of the watch the man takes care of his money, or of an equal sum which he has in bank. Admit also that, if a twenty-to-day is worth more than the twenty to come when the man shall pay, so also a twenty on the day when the man does pay is worth more than the twenty which our uncle had a month before (that being "gone," as friend Aquinas says); yet we must consider that he has been sitting in his office many days, waiting for that man to come for the trifling accommodation; and then he has had to sit there a whole month longer waiting for the man to come for his watch, not daring to absent himself lest the man might have come sooner. Can we expect him to do all that, and pay rent for his office besides, for the fun of it? Hardly!

What, then, is the service which our uncle has rendered to that man? I answer, that of a purveyor. Just as your grocer purveys your sugar, which he has bought at wholesale and lets you have at times and in quantities to suit your convenience, so the pawnbroker has bought (earned) a quantity of money which he lets people have in such sums and at such times as they may choose. The only essential difference, which, however, does not affect the question before us, is that in the pawnbroker's case the transaction does not end with the purveyance of the money; he must again await the convenience of his customer to receive the money back and return the watch. I have somewhere read that "they also serve who only stand and wait." If any one is perverse enough to say, in order to say something, that the man had about as much trouble in going for the money, doing without his watch, and repaying the money, that perverting person must be made to perceive that the man did all that for his own accommodation. Moreover, he had the pleasure of going to the picnic.

There is the long-sought justification of interest in a nutshell, as it were, and it has been lying around loose for thousands of years. The pawnbroker has rendered service and "the laborer is worthy of his hire." Interest is just; it is the wage of service. On no other ground can it be justified, for money can be justly claimed only in return for service rendered.

*The claim of a child on its parents for service which it cannot return may appear to be an exception. I think this is a transferred or inherited claim and will not stop to discuss it.

The principle applies to all cases of interest (not to all rates, that is a question of amount of wage for the service). The "capitalist" or banker who lends on mortgage is only an evolved pawnbroker. A house and lot cannot be brought to him and locked in his safe, so he takes a deed of sale, with a proviso for resale on payment of debt and interest, and that is a mortgage. The client in this case has the advantage of using the pledge during the term. The lender renders service, firstly, by purveying money; secondly, by waiting for its return; the interest is the wage of that service, at least that part of the charge which is true economic interest. There are sometimes other elements which appear as interest, which I will now explain.

In considering this matter philosophically, as I am trying to do, it is necessary to discriminate. Apparent interest, the quantity which is paid under that name, is composed of three elements, as follows:

1st. True or economic interest. This is the wage of service of purveyance (trouble, work and expense involved).

2d. Profit (or plunder); of this anon.

3d. Insurance. This is the wage of the service rendered by him who assumes risk of loss for the accommodation of another. It is reduced to a minimum when the security is good, to zero when the security is perfect.

The second element is perhaps usually the greater in amount, at least when security is not very poor. It requires explanation, not because it affects the gist of our question, but because it is so interwoven with true interest as to appear to be a part of that. In fact all of the so-called elements of political economy are complex, the one overlapping the other or changing its character in the different stages of commercial operations, and I am convinced that the only way in which the student can avoid bewilderment and inconsistency is to keep constantly in mind the fundamental axiom that money can be justly claimed only in return for service, and its corollary that all just payments are the wages of some service.

That which, in trade, is called profit is not a simple quantity. When a man deals in a commodity and finds after paying all wages of production, carriage, and purveyance (his own part in the transaction), that he has still a balance in hand, he calls that profit. Many count profit before deducting their own wages, but that is incorrect. It is now in order to ask, if all wages of service have been paid, how is profit justified? I reply there is yet a wage of service which we have not counted, namely, the risk of trade by which the trader sometimes loses his own wage and sometimes more than that. Profit is a compensation of the risk of loss, the wage of the service of him who assumes a risk for the benefit of others, whether it be risk of fire, etc., of which he may be relieved by paying an insurance company, or of deterioration of goods, or of fluctuation of the market. Profit is therefore just.

Money, as I have said before, is, unfortunately, a commodity, and as such is subject to the usual effects of the ratio of supply and demand; hence profit is an element in apparent interest.

While the wage of service of any kind is just, whether it be called interest or profit or insurance or whatsoever, an exorbitant charge for such wage is *plunder* to the extent that it is exorbitant. Just what is a proper wage for any given service must be left to the individuals concerned to decide. There is no standard for that; but when a man takes a mean advantage of circumstances which no man can control, he is unjust, and still more so when he, alone or in association, purposely brings about the circumstances which enable him or them to oppress their fellows. These things are done, more or less, in all kinds of business.

Interest is just—that is fair interest, fair wages for service rendered. That injustice often arises from it only places it in the same category with other human affairs. True, the Shylock often takes advantage of circumstances, and exacts his pound of flesh with relentless rigor, careless though blood may flow; but it is not the man who does so. Oh, no! it is the priest of the Temple of the god Business, the prime canon of whose cult is to get the greatest possible amount of service in return for the least possible, to charge "all the traffic will bear." The money-lender is even as others are.

That some men are able to live on the interest of their money, while not rendering service equivalent to that which they receive, is in fact a gross injustice. It is due, however, not to any inherent injustice of interest, but to defects in our social condition by which it becomes possible for some to "make" enormous wages for relatively small service, and so to accumulate fortunes far beyond their deserts—in short, to plunder their fellows, and the wrong is perpetuated by our laws of bequest and inheritance, which require thorough revision.

It is this state of affairs which leads to that great misfortune, a bonded national debt, which lays a burden on generations unborn and robs those who have nothing but a wickedly curtailed right to toil, of a part of the product of their toil. The child is born into a land in which is no place for the sole of his foot except he buys it by toiling for others and, as if that were not already too much, he must toil yet more to pay the interest of debts which he did not contract, and many of which were contracted on Shylock terms, without good reason, and from which he derives no benefit.

One cause of scarcity of money at certain times and, consequently, of high interest, is the practice of hoarding, and it is one advantage of paper money that it is less liable than metal money to be thus withheld from performing the function for which it was created by the community. I cannot say if it would be practicable to make hoarding of money a crime in law, but it is certainly wrong. The money substance may belong to the holder of it, but the money quality does not. Those who want to hoard should buy some kind of imperishable property, such as bullion or diamonds, and let the money circulate.

The vindication of true interest is not a great achievement. The populace, in all times and all countries, have intuitively recognized its justice. It is the manifest injustice perpetrated in the guise of interest, the element of

plunder arising from the commodity quality of money, the abuse of the power given by circumstances, the artificial production of conditions for the exercise of that power, and the uncharity of interest, especially high interest, on money or goods borrowed for personal needs, that have caused distrust in thinkers both lay and clerical.

I have always had a strong suspicion that a general and enduring popular belief contains a kernel of truth. Women, children and the masses often feel truths which learned men will not feel and cannot see. C. H. AARON.

Mining Notes from Siskiyou.

TO THE EDITOR:—Owing to the bountiful supply of water this last winter, the placer miners throughout this county are doing well this season and some rich clean-ups are expected. Austin & Raynes are pushing work on their blue gravel drift mine on the mouth of Greenhorn creek. Their shaft is 107 feet to bedrock and, although they have run one drift 105 feet south from the shaft, they have not succeeded in crossing the channel yet. They have been running two shifts now for several months, night and day, developing the mine, and it has paid a dividend from the beginning, which speaks well for the future of the property. Two drifts have been run from the shaft, one 85 and the other 105 feet, each 12 foot face, which will give ample working room when they commence breasting out. The pump formerly used, being too small to handle the water, is now being replaced by a larger one of sufficient capacity to keep the mine dry. They will have the new pump in place in a few days; then work will be resumed and a double force of men will be put to work to open up the mine as soon as possible. The channel where the mine is located is very wide and the old miners, who claim to know, say it is immensely rich.

About a quarter of a mile west of this mine, on the same channel, C. L. Murray & Co. are sinking a shaft to tap the pay gravel. They reached the depth of 56 feet, where the water drove them out, and they suspended work until they can get the proper machinery in place to handle the water. It is known, by shafts which have been sunk on this ground in years past, that bedrock is not near so deep as it is at the Austin & Raynes mine. Mr. Murray expects to reach bedrock at the depth of 60 or 65 feet.

There are some very promising looking quartz prospects on the divide between Greenhorn and Cherry creeks and the ore from them assays very well. The ledges are small but well defined and have the appearance of being permanent. Several mining men have visited this locality of late, but so far no recent transfers of mining property are reported. ALEX. QUARTZ.

Yreka, June 6th.

The World's Petroleum Supply.

Petroleum is produced in various countries, either in its raw state springing from natural sources—as, for example, in the United States, Russia, Canada, Dutch East Indies, Austria, Roumania, Peru, Argentine Republic and Ecuador—or produced by the distillation of bituminous schist, as in Italy and France. Up to the present the United States has been the most important center of the petroleum production. The *Moniteur Des Interets Matériels* says that the statistics establishing the yield during the last months of 1892 seem to indicate a gradual exhaustion of the sources, as the average monthly supply in 1892 was only 87,711 gallons, compared with 94,980 gallons in 1891. On the other hand, the production of raw petroleum in 1891 and 1890 was respectively 34,000,000 and 45,000,000 barrels, or a falling off of 11,000,000 barrels in 1891. In spite of this the exports of petroleum, raw and refined, have followed, thanks to the employment of tank steamers, an ascending scale, and amounted to 740,905,237 gallons in 1892, as compared with 667,000,000 in 1891.

In spite of the diminished production, the prices, instead of rising, have experienced a fall owing to the keen competition of Russian with American petroleum, hence the abandonment of certain springs in the United States.

At Baku, in Russia, the production is very great, and even exceeds the demand. No greater proof of this fact can be evinced than the low prices lately quoted, viz., one-half copeck per pound (36 pounds avoirdupois) for raw petroleum, and 7 copecks free on railway trucks for refined petroleum. During the first nine months of 1892 the production of raw petroleum in the Apsheron Peninsula amounted to 213,560,157 pounds, as compared with 213,056,000 pounds for the corresponding period of 1891.

The present depressed condition of the petroleum market in Russia will be improved, it is expected, by the formation of the syndicate that has been constituted by the seven principal producers of petroleum at Baku under the presidency of M. M. Nobel freres.

With respect to petroleum production at Baku, Mr. P. Stevens, Her Majesty's consul at Batoum, in a report to the Foreign Office, dated the 1st of March, states that an oil well has recently commenced to flow at Baku, which, at its present rate of production, considerably exceeds the daily output of all the largest wells that have hitherto been in activity in the Apsheron Peninsula.

It is estimated that the well in question is delivering, as near as possible, 1,000,000 pounds, or 17,742 tons of crude oil a day, but owing to the almost insurmountable difficulties experienced in getting a flow of this magnitude under control, most of the oil is running to waste into an adjoining lake known by the name of Romani.

The well is situated one-fourth to one-half mile farther eastward on the peninsula than any of the other wells, and, it would appear, opens up a fresh territory comprising several hundred acres of land from which no oil has yet been extracted.

From the point of view of the importance of the production, the petroleum supplies of Canada take the third place. From the 1st of January to the 30th of November, 1891, 192,700 barrels of raw petroleum and 248,025

barrels of refined were exported. During the same period of 1892 these shipments amounted to 182,371 and 279,823 barrels respectively, a total production in the first 11 months of 1891 equivalent to 805,687 barrels of raw petroleum, and in 1892 to 917,561 barrels. Petroleum has been found in Quebec, Nova Scotia and New Brunswick, and particularly in the Northwest Territories, where it seems certain that there is an immense unexplored oil region. It is, however, in the county of Lambton, whence most of the oil has been, and still is, obtained. The township of Enniskillen is one of the largest oil-producing districts, and the oil is obtained there at a depth of from 370 to 500 feet. The first flowing well was struck in February, 1862, and before October of the same year there were no less than 35 wells. As there was no accommodation for the storage of this enormous flow, there was a frightful amount of waste, and it is calculated by one authority that between the dates mentioned no less than 5,000,000 barrels of oil floated off upon the water of a neighboring creek.

The petroleum supplies of the island of Sumatra have only recently been exploited. The product of one district amounted to 20,000 ten-gallon boxes in a year. According to the most recent analyses (*vide C. T. J.*, No. 306, p. 210) the Langkat petroleum is of excellent quality, and moreover they are derived from lands the extent of which is 40 times greater than those in Russia.

According to official statistics, published by the Austrian Minister of Agriculture, there were in Galicia, in the year 1891, 199 establishments engaged in the production of petroleum, and 79 ozokerite mines, supplying together a total quantity of 93,875 tons, of an estimated value of £491,000.

In Italy and France petroleum is obtained by the distillation of bituminous schist. In 1891 the Italian production was 1155 tons of petroleum, while in France the amount of the product for 1889 was 194,000, as compared with 174,000 in 1888.

The yield in Roumania barely attains a value of £2400, although this amount might easily be increased, seeing that there are vast numbers of beds from which it can be obtained, and that the oil itself is of excellent quality. The explanation of the small supply lies in the fact that the government insists, in the case of crown lands, upon the payment of a royalty immediately upon the signing of the contract, and even before any petroleum has been found.

The petroleum beds in Peru are of vast extent and are beginning to attain considerable importance. The London and Pacific Petroleum Co. has works extending over a distance of two miles along the coast, and owns 26 pits which are in working, having a depth of from 70 to 500 feet, and producing 900 barrels a day.

In the Argentine Republic, 12 pits have been sunk in the department of Lujan, province of Mendoza, of which three have yielded excellent results. The company working these mines since 1890 has produced about 1500 tons of petroleum.

At Cachenta, in the province of Mendoza, in the Argentine, a considerable petroleum industry has sprung up during the last two years. In this district there is a promise of great mineral wealth, but as yet it has been worked only in a desultory manner. There seems to be a future before the petroleum industry. Up to the present time three successful borings have been made, and the total output since the first boring, in April, 1890, has been 1500 tons. The oil is conducted through pipes to the storage tanks at San Vincente. It finds a ready sale at the Rio Cuarto and Mendoza gas works and at the Argentine Great Western railroad. This railroad has 12 locomotives which use the oil as fuel.

In the republic of Ecuador numerous petroleum beds are known to exist, and these are of considerable extent. In certain places the oil springs from the ground and forms pools and streams, which eventually find their way into the sea. A syndicate has recently been formed with the object of obtaining the concession of these sources of petroleum, the product of which is said to be of a very good quality.

In British Burma it appears that there are now 602 petroleum wells, an increase of 92 since 1888, but there are distinct signs of exhaustion. The fact that the aggregate production of the richer wells has fallen off, while that of the poorer ones has increased, although many new wells have been opened, is regarded as the surest indication of the approaching decline in the industry. The drilled wells worked by the Burma Oil Co. and the Burma Oil Syndicate have given very satisfactory results. In 1890 the total out-turn amounted to over 3,670,000 viss; but the rate of progress during 1888, 1889 and 1890 has not been maintained during the past two years. The history of the industry shows that the production of the oil-field steadily increased from the beginning of the century until about 1873, when it began to decline, rising again in 1885 and coming practically to a standstill in 1891.

The Cause of Ore Chutes.

For years I, like probably many others, have pondered over the peculiar distribution of ore in the limestone contact mines of the Rocky mountains, and particularly as exhibited at Leadville, Red Cliff and other mining sections of Colorado. Why are the deposits in distinct chutes or channels, and what cause gave these chutes the trends or courses they have? These are questions that must have occurred to every mining man, and doubtless were dismissed by the majority without any solution to the question. Certainly these questions intruded themselves upon the mind of the writer hundreds of times before an apparently satisfactory answer was evolved.

In examining ore chutes occupying planes between blue and brown lime, or blue limestone and shale or porphyry, it will be noticed that, while the ore chutes seemingly occupy troughs or channels in the bedding rock, these are not depressions or waves in the formation, but arbitrary replacements of the limestone. The hanging-wall or cap is invariably regular, and does not conform with the bedding plane of the ore, neither does it separate or distend over the ore, so as to have produced an opening in what was

originally a closed contact, and might thus have been thought to have facilitated the creation of an ore chute.

Another feature about ore chutes that has led me to considerable speculation is that they are invariably thicker on one side than on the other. In other words, the swelling or thickest part of the chute is nearer to one edge than the other. Thus at Robinson and other places I have found that an easterly and westerly ore chute, 150 feet long, would reach its maximum thickness at 20 to 30 feet from the southern edge, thinning gradually to the northward until it feathered out entirely.

The course of ore chutes differs in different districts. At Leadville they have a general northeast course; at Rico they run southeast. In all districts they are more or less parallel—that is, when a chute is considered relative to its neighbor, although the same may not prevail as to an entire system, as at Leadville where there are probably no less than 30 distinct ore chutes or channels. In the northern portion of this district the course of these channels is, if anything, a trifle south of east. The great ore chute that traverses the Morning Star and Maid of Erin mines has a course as nearly east and west as a line can be drawn, the Iron Hill ore chutes have a course north about 50° east, while farther southward, the Rock Hill chutes show a trend north, 20° east only. If continued, they would all unite at no very distant point. This, however, is not at all probable.

Whatever the theory as to the genesis of the ore of the different mining districts, there is no question but that the ore was deposited from mineral-charged waters, which found an opening and opportunity to circulate in the contact plane. If there were originally no troughs or depressions in the limestone, it would seem that the contact plane generally should have been mineralized, instead of channels. In fact, whether the flow was induced by gravity, hydrostatic pressure, capillary attraction or any other agency, the facilities for mineralizing one portion of the contact plane were as good as for another. Following on this line of reasoning, and not wishing to enter the more complex field of speculation involving the agency of electric currents, etc., a cause for the deposition of the ore in channels was sought in the character of the limestone itself. It then occurred to me that in the deposition of the limestone, certain belts or zones incorporated more organic matter than others. What the movements were of the paleozoic sea, and the extent of its animal and vegetable life is a matter of speculation, but it is easy enough to imagine aggregation of organic matter in lines conforming with the ebb and flow of the tide, or possibly the successive lowering, or alternate lowering and rising of the sea. Such concentrations are now represented by ore chutes. It is to such an origin of the ore chutes also that an explanation can be found to the unequal thickness of the chutes, and to their strength along an axis parallel with the ancient shore lines.

The Leadville district, during the carboniferous age, doubtless was a bay of the Paleozoic sea, with Mount Massive on the west and Homestake and others more northerly. This gave, in the northern part of the district, a high tide line nearly east and west, and more southerly, a tide line north and south to conform with the base of Mount Massive and Elbert, which is with the meridian.

If the proposition of an unequal distribution of organic matter in the limestone is tenable, then we have no difficulty in solving the question why ore is deposited in chutes, for the minerals in solution as sulphates would find ready reception upon coming in contact with carbonaceous matter.

I am further confirmed in this belief of the cause of ore chutes by the character of the ore yielded by different chutes, which varies greatly. Some are rich in lead, but have very little iron associated with them; others are highly ferruginous, but devoid of lead. The Silver Cord and the Florence and Little Ella ore chutes contain considerable gold—one in the extreme north, the other in the central and the Florence in the southern portion of the district. Twenty or thirty ore chutes between these are devoid of gold. There is no doubt but that the same mineralizing agency that produced one of the ore chutes produced all of them, but that the re-agents necessary to transfix the mineral in solution were not equally and proportionately present in the different channels in the limestone, hence the variation in the composition of the ores of different chutes, although the same are within but a few hundred feet of one another.

My theory on this proposition I believe is further verified by the almost unlimited area in the west, where limestones and eruptive rocks come in contact under conditions not unlike those of Leadville and elsewhere, and that have unquestionably been subjected to mineralizing influences, but not possessing the necessary re-agents, retaining none of outflowing wealth.

This latter proposition is, in a measure, exemplified in the barren belt of Southern Carbonate Hill, over a third of a mile wide, and, with strong ore chutes on either side, and practically the same causes and effects noticeable at Leadville, prevailed with slight modifications in all the other sections of the west.—A. F. Wuensch in Mining Industry and Tradesman.

THE NEW YORK *Sun* prints a complete and very interesting review of the wheat situation throughout the world. It points out that Europe's requirements are each year about 14,000,000 bushels greater than the year before, on account of the increase in population. Wheat production in Europe is decreasing, and the present year's requirement of 368,000,000 bushels, or a little over a million bushels per day, will probably be less than what will be needed for years to come. The *Sun* says, that with a liberal estimate India may furnish 40,000,000 bushels. If our crop yields 450,000,000 bushels we may be able to spare, with the surplus of 1892, as much as 126,000,000 bushels. On the most favorable showing there must be a deficiency of 64,000,000 bushels, and then leave no reserves to be carried over to 1894. The *Sun* has a reputation for accuracy and reliability in these annual reviews, and we may accept its statement of the situation as substantially correct.

Mechanical Progress.

Armor Plates Pass the Premium Test.

Another highly successful trial of armor plate for the navy took place at the Indian Head proving grounds on May 11th. The plate tested is intended for the *Amphitrite*, and represents a group of about 1000 tons of armor of the same general class and thickness, for which the government is to pay \$510 a ton. The plate was of nickel steel, nine inches thick, made at the Carnegie Works. The trials were made for the acceptance and premium tests. The plate was fired at by an eight-inch-high power rifle gun. Two shots were fired. Both projectiles were of the armor-piercing type and weighed 250 pounds each. In the first round, 61 pounds of powder were used, the velocity being 1391 foot seconds. The plate and about one inch of the backing were cracked, but no similar damage was done to the plate. In the second round 85 pounds of powder were used, the velocity of the projectile being increased to 1672 foot seconds. The shot went through the plate, and partly showed through the backing, but did not get through the latter. No signs of a crack in the plate were visible after the firing, the holes made by the projectiles being clean cut, with only the usual fringes on the face. Altogether, the trials were highly successful.

The *Amphitrite's* plate has the record of being the first one which has passed the premium tests. Under the terms of the contract the manufacturers are entitled to extra compensation at the rate of \$30 a ton for ballistic properties of all armor in this group. It happens, however, that the Carnegie Company will not receive a premium in this particular case, as the premium will, under the regulations of the Navy Department, be used to defray the expenses of experiments with this and other plates recently tested. American Manufacturer.

CURBING SHAFTS AND WELLS.—A new method of lining and curbing shafts and wells is now being tried in Germany, says *Engineering*. In this, blocks of molded concrete are employed, which form segments of a circle or an oval, varying in size according to the dimensions of the shaft or well, and weighing from 8 cwt. to 12 cwt. each. These blocks have at each side a round fluting, with a channel at the top, and a corresponding but smaller semi-cylindrical roll or beading at the bottom; they have also two drill holes, one running vertically and centrally, and the other horizontally from back to front at the base. The vertical drill hole enables a rod with a hook or ring to pass down and be intersected by a bolt running through the horizontal drill hole, thus holding the rod and supplying the means of hoisting or lowering the blocks into their places. When a complete round of segments is formed (the blocks break joint like ordinary brickwork), the vertical flutings are rammed with a cementing material, and the space between the round and the natural wall of the shaft is packed with concrete. Before laying the next round of blocks, a thin layer of cement is placed in the channel on the top of the blocks beneath, into which the projection of the upper blocks fits, the joints thus becoming perfectly tight, and forming a solid lining through which water cannot penetrate. This system, it is said, has already proved a success in several colliery shafts in the Saarbrocken district, belonging to the Prussian Government, which have been provided with linings in the manner described, with satisfactory results.

THE IRON BUSINESS.—Iron and iron products of all kinds continue to sell at extremely low prices. Beyond a doubt the point has now been reached beyond which values cannot be depressed without entailing disaster. Never in the history of the world have iron and steel been so low in price as at present, and still the tendency is downward. The phrase "Bedrock has been reached," although stereotyped in most offices, has become worn by long usage and no longer means anything, except that the writer knows nothing about the matter. It is certain that a good many concerns in this country are engaged in manufacturing iron and steel at an absolute loss. It is in business as in nature—the fittest survive. Not that those best entitled to success succeed, but those best fitted to carry on business. Improved machinery has had more than anything else to do with the present low prices of iron, steel and their products. Only wealthy concerns can adopt all the latest and best labor-saving devices, and, in consequence, the small manufacturers will be the first to succumb. Besides this, some plants are better located to economically

manufacture than others. In the meantime strikes for higher wages are out of place.—Chicago Journal of Commerce.

COPPER-PLATING SHIPS' BOTTOMS.—James D. Darling, of Frankfort, Philadelphia, has been developing a method of electroplating the hulls of steel vessels with copper to keep them from fouling and to do away with the necessity for dry-docking, scraping and repainting. He proposes to plate the bottom of iron and steel ships with a continuous sheet of copper that will be so firmly attached to the iron or steel that there will be no danger of its being torn off by accidental grounding on bars, etc., and that it will have no seams or joints to admit sea water and set up galvanic action. The usual method of depositing copper electrically on iron or steel could not be used for this purpose, because the thick coat of copper required when thrown down from the ordinary sulphate solution would be very rough and uneven on the surface, more or less porous and entirely unfitted for the purpose. Mr. Darling has discovered a new method of depositing copper by which a perfectly smooth surface is obtained and by which a very dense and firm deposit is made. The White Star Steamship Company has been investigating it with a view to using it on their new ships, and it has also been submitted to the United States Navy. Arrangements are now being made to plate a small vessel, so that a practical trial may be given to the invention.—Iron Age.

FUEL OIL ON AN OCEAN STEAMER.—Last week we made a brief mention of the arrival of the James Brand, a tank steamer, from across the Atlantic, having made a successful experiment of using oil as a fuel. The captain of the vessel reports that for three days the Brand used oil for fuel, and the manner in which it worked gives conclusive evidence that it will be a complete success. The manner in which the fuel is fed to the boilers is by jets of steam and fuel petroleum which meet under a line of brickwork below the boilers. Sufficient heat can in this manner be generated to force everything to a white heat, while the temperature can be regulated by the engineers according to the speed required. This is the first attempt of a vessel to cross the Atlantic by generating steam with oil as fuel instead of coal, and the result may be very far-reaching, especially as the Brand is not an experiment but a regular cargo carrier—in fact one of the largest, the carrying capacity being 1,500,000 gallons. The vessel registers 3780 net tons, and is built of steel throughout. Her length is 345 feet over all, 43½ feet beam, and 29½ feet depth of hold, with triple expansion engines of the latest and most approved type, and Scotch steel corrugated boilers.—American Manufacturer.

WIDE WAGON TIRES.—It is only a question of time when broad wagon-tires will be seen on all our wagons employed for hauling merchandise and freight, the same as may be seen in all the capitals of Europe. The Ontario Department of Agriculture has sent out a valuable special report, or bulletin, setting forth the treatment necessary to make, as well as to maintain, good roads. The report says the repairing of roads once a year (the usual plan) is wrong in principle. It is all the more objectionable, as almost always it is done in the spring, the good effects disappearing before the time for fall and winter travel sets in. The report strongly commends the movement in favor of wide tires for draft vehicles. It says it has been proved by repeated experiments that wheels with tires two and one-half inches wide cause double the wear of wheels which have four and one-half-inch tires. The wide tire has a tendency to roll the roadbed and keep it smooth at the same time, while the narrow one cuts it up and requires more hauling force for the same weight of load, besides spoiling the thoroughfare. Most of the European countries have laws regulating this matter.—Horseshoer and Hardware Journal.

W. K. VANDERBILT'S new yacht "Valiant," which is to replace the sunken "Alva," was launched at Birkenhead, near Liverpool, last week. She has been built by Laird Bros. and is a steel twin-screw vessel of 2400 tons. The principal dimensions are: Length between perpendiculars, 310 feet; beam, 39 feet; depth, 25 feet 6 inches. She will have two sets of triple-expansion engines driving manganese bronze screws. The horse-power to be developed will be 4500, which will insure, with moderate forced draft, a speed of 17 knots, while under natural draft the vessel will steam 15 knots. The "Valiant" will be fitted with all modern improvements, including the electric light and two powerful search lights.

Scientific Progress.

Lasting Character of Soil Pollution.

Dr. Lauciani, in his work on ancient Rome, says that while a system of garbage collection existed under Roman rule, the disposal of refuse was as crude as it is in many modern towns and cities. That this disposal method was regarded as a nuisance at a very early period is made evident by the fact that sanitary laws were passed 2000 years ago that were intended to at least mitigate the trouble.

Some of these laws, graven on stone, were unearthed by Dr. Lauciani in his excavations, and the text of one of them reads, "C. Centius, son of Caius the Praetor, by order of the Senate, has set up this line of terminal stones to mark the extent of ground that must be kept absolutely free from dirt, and from carcasses, and from corpses. Here also the burning of corpses is strictly forbidden." On the bottom of this stone, in red letters, some probably near resident had written, "Do carry the dirt a little farther; otherwise you will be fined."

But this bounding line, beyond which any foul matter might be cast to putrify under a Roman sun, was only 400 feet from the city walls, as erected by Servius Tullius. When Dr. Lauciani dug up these stones, on June 25, 1884, and about 2000 years after the use of this area for refuse disposal, the soil was still so polluted and the stench arising from it so horrible that even his workmen, inured to such work as they were, found it absolutely unbearable and had to be relieved at frequent intervals.

The dumping-ground near the Esquiline cemetery, including the present cemetery itself, was the greatest of these nuisances, and so long ago as the beginning of our Christian era the Roman rulers found it necessary to cover this area with 25 feet of soil and to convert it into a garden.

The long and active survival of disease germs in soil was also claimed in excavations made inside a cofferdam uncovering the bed of the Tiber alongside the bridge leading to the Castle of St. Angelo, in Rome. Here, in successive strata, were found coin and other relics, fixing the age of the deposit down to the fourth century A. D. The soil as it was slowly removed was piled upon an adjoining wharf and then taken away. When the very lowest and oldest of all the strata disturbed was so disposed of, an epidemic of typhoid fever broke out among the workmen and those living in the immediate vicinity. The result of careful examination is said to have shown that the trouble came from this lowest strata, and that disease germs that had been lying dormant at the bottom of the Tiber for nearly 1500 years were still active for evil and proved their vitality. This statement, as far as the survival of the germs of typhoid is concerned, has been disputed. Considering the difficulty of detecting these germs in refuse recently deposited, there is ample room for doubt as to the exact point in the strata that caused the trouble observed.—Engineering News.

Spots on the Sun.

Henry M. Parkhurst has sent the following to the *Herald*: "The large group of spots referred to in the telegram of Professor Holden last Friday, is now passing off the western limb, but it is so vast in extent that a portion of it will be visible several days. The visibility of the spots to the naked eye, reported by Professor Holden, is not due to the size of any individual spots, but to the large number in a cluster, surrounded by the penumbra.

"Dr. Dick, after many years' observation of solar spots, came to the conclusion that a single spot in order to be visible to the naked eye must be at least 50,000 miles in diameter, or six times the diameter of the earth. The principal cluster in this group is very much larger than that, and it is not improbable that it will continue long enough to pass around the disk and reappear in a little more than two weeks on the eastern edge.

"The largest single spot now visible is a little northwest of the center of the sun. It can be seen with a good opera glass with the eye suitably protected. There are also other spots along the line of the sun spots, the largest of which is one which has appeared at the eastern edge since the telegram of Professor Holden. If the theory is correct, that it is the spots at the eastern limb of the sun which most affect the earth's meteorological condition, it would seem that it is to this spot, rather than to Professor Holden's group, that the present hot wave is due.

"The whole surface of the sun seems to

be unusually active, even for the maximum of solar activity, and Dr. Veeder will have ample opportunity to compare results with the conditions of an exceptional season."

Luminous Discharges in Electrodeless Vacuum Tubes.

An abstract of a paper by Mr. Rimington, read before the Physical Society, is given in the *London Electrician*, May 5th, accompanied by a few illustrations. He states that luminous rings produced in vacuum tubes by discharging Leyden jars through coils surrounding them had been attributed by Tesla to the electrostatic action of the surrounding wire, rather than to the varying magnetic induction through the rarefied gases. The present author thinks that the latter cause is the chief one, but that a supposed electrostatic field greatly assists their production.

An experiment was shown in which a tube was placed in a coil through which Leyden jars were discharged, the spark gap being adjusted to produce no luminosity. If, then, the terminals of the coil—that is, the Leyden jars—are also connected to one or both of two metal plates between which the coil is placed, in such a way as to increase the electrostatic field through the bulb, bright rings immediately appeared. In another experiment two loops of wire in series were used and were put on the bulb in such a way as to produce a large magnetic effect, but a small electrostatic field. Bright rings appeared, while, if the magnetic effects opposed each other and the electrostatic field was increased, no rings were seen. The original paper treats this subject mathematically at some length; he shows that the time integral is roughly proportional to the fourth root of the capacity; large jars are therefore only slightly better than small ones. Mr. Trotter discussed the difference between these effects and those obtained by Swinton. The latter, Mr. Rimington said, were quite different and were due to different causes, namely, to the phosphorescence of the glass.

MOISSAN'S DISCOVERIES.—The name of Henri Moissan has figured very prominently in the scientific world for some time, and not without reason, for the distinguished young French savant has lately made a series of experiments and discoveries whose interest is only equalled by the rapidity with which they have been successively placed before the public through the medium of the celebrated Paris Academie des Sciences. On February 6th Mons. Moissan read a paper, according to which, he claims, by means of the electrical furnace capable of generating the extraordinarily high temperature of 300 degrees Cent. that he lately invented, to be able to manufacture the diamond. On February 13th he contributed one memorandum upon a Canon Diabli diamondiferous meteorite, and another upon the presence of graphite, carbonado and microscopic diamonds in the blue earth of Cape Colony, while on February 20th he utilized the furnace mentioned for the purpose of obtaining, within ten minutes, an ingot of the rare metal uranium weighing 250 grammes. Upon this occasion he pointed out that he had ascertained that a combination of this metal with carbon ignites spontaneously in the atmosphere, yielding a white light; and, by way of practical illustration, he, much to the alarm of his select audience, slyly shook a bottle containing a preparation of this class, with the result that a slight explosion followed. When the assembly was once more prepared to calmly listen to Mons. Moissan that gentleman exhibited ingots of chrome and manganese prepared in a few minutes in the way the uranium bar had been, whereas the ordinary reduction process, he observed, absorbed a comparatively long time. All things considered, the French scientist believes that the use of higher temperatures, which can be developed by a dynamo-electric machine actuated by natural water power, will become an important feature of the art of metallurgy.—The Age of Steel.

SWEDISH IRON, which is soft, yet strong and ductile, is almost free from phosphorus and sulphur. It is held to be practically inexhaustible, though taken out at the rate of about 1,000,000 tons a year. It is found all through the country, though chiefly mined in central Sweden, in the Dannemora district. Several of the heights as truly deserve to be called iron mountains as those of Missouri, and there is one in Gellivare, in Swedish Lapland, beyond the Arctic circle, where the ore occurs in four gigantic strata, that would supply nearly all the iron the country would require in a century.—Tin and Terne.

MARSHUTZ & CANTRELL

The Patentee and Manufacturers
cordially invite miners to critically
examine and pass judgment upon
this improved system of milling
and amalgamating ores in the fol-
lowing particulars:

1. The cost is less than one-half of
stamps of same capacity.
2. The freight to mine is less than
one-half of stamps.
3. The cost of erecting is less than
one-fourth of stamps.
4. The power to drive it is less than
one-half of stamps.
5. The wear is less than one-quarter
of stamps.
6. There is no wear except on
shoes and dies.
7. In point of amalgamation it is
superior to any other machine
in use.
8. In its simplicity of construction.

We challenge competition with
Stamps, Ball Pulverizers or and
other ore crushing machines now
before the public.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved
Concentrating Belt manufactured in San
Francisco. We keep always on hand
Belts suitable for the Triumph and Frue
machines, but can make any length or
width desired. The advantages of these belts over
any others will be readily seen by practical millmen.

First, the flanges or edges of our belt stand at an acute
angle inrolling toward the center, and therefore readily
conform to the change of direction while passing over
the end rollers; thus the vexation and loss caused by the
frequent breaking of the flanges of the old style belt is
practically done away with. Again, our belts, at intervals
of two to four feet, have a very slight rifled surface for the
space of three inches, which tends to equalize the pulp
on the belt, and prevents it from banking on the sides and
forming channels through the center. These slight rifles
also save very fine sulphurets and the quicksilver that
would otherwise escape with the tailings from a belt,
the surface of which is entirely smooth. We can safely
say that it is a better concentrator belt than has ever
been manufactured. It will last much longer and
will handle more pulp. We also manufacture smooth belts with same flanges when desired.

H. G. BLASDEL, Jr., Manager, 419 California St., San Francisco.

FRISBEE-LUCOP MILL CO.,

—MANUFACTURERS OF—

Centrifugal Roller Steel Mills,

FOR PULVERIZING ORES, WET OR DRY,

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

ASSAYERS' MATERIALS, MINE
AND MILL SUPPLIES,

ALSO CHEMICALS, AND PHYSICAL, SCHOOL AND
CHEMICAL APPARATUS.

63 & 65 First St., cor. Mission, San Francisco

We would call the attention of
Assayers, Chemists, Mining Com-
panies, Milling Companies, Pros-
pectors, etc., to our full stock of
Balances, Furnaces, Muffles, Crucibles, Scor-
ifiers, etc., including, also, a full stock of
Chemicals.

Having been engaged in furnishing these sup-
plies since the first discovery of mines on the
Pacific Coast, we feel confident from our experience
we can well suit the demand for these
goods, both as to quality and price.

Agents of the Denver Fire Clay Co. and
for the Morgan Crucible Co., Battersea,
England. Also for E. G. Deoniston's Silver
Plated Amalgam Plates. The plates of this well-known
manufacturer are thoroughly reliable, and full weight
of Silver guaranteed. Orders taken at his lowest prices.
Our Illustrated Catalogue and Assay Tables sent free
on application.

JOHN TAYLOR & CO.

Books on Assaying.

By C. H. AARON.

Part I.—Gold and Silver Ores.

SECOND EDITION—PRICE \$1.

This work is written by an experienced metallurgist
who has devoted many years to assaying and working pre-
cious ores on the Pacific side of the American Continent.
He writes whereof he knows from personal practice, and in
such plain and comprehensive terms that neither the scientist
nor the practical miner can mistake his meaning.
The work, like Mr. Aaron's former publications ("Testing
and Working Silver Ores," "Leaching Gold and Silver
Ores") that have been "successfully popular" is written in a
condensed form, which renders his information more readily
available than that of more wordy and less conscientious
writers. The want of such a work has long been felt. It
will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Ma-
terials; The Assay Office; Preparation of the Ore; Weighing
the Charge; Mixing and Charging; Assay Litharge; Systems
of the Crucible Assay; Preliminary Assay; Dressing the
Crucible Assays; Examples of Dressing; The Melting in
Crucibles; Scoriafication; Cupellation; Weighing the Bead;
Fining; Calculating the Assay; Assay of Ore Containing
Coarse Metal; Assay of Roasted Ore for Solubility; To
Assay a Cupel; Assay by Amalgamation; To Find the Value
of a Specimen; Tests for Ores; A Few Special Minerals;
Solubility of Metals; Substitutes and Expedients; Assay
Tables.

The volume embraces 130 12mo. pages, with illustrations,
well bound in cloth; 1893. Price, \$1, postpaid. Sold by
DEWEY PUBLISHING CO., Publishers, No. 220 Market
Street, San Francisco.

Parts II and III.

Gold and Silver Bullion, Lead,
Copper, Tin, Mercury, Etc.

SECOND EDITION—JUST OUT.
Price \$1.75.

This book is entitled "Assaying—Parts II and III," and is
separate from Part I, and treats of Gold and Silver Bullion,
Lead, Copper, Tin, Mercury, Zinc, Nickel, Cobalt, etc.

Table of Contents:

Gold and Silver Bullion; Apparatus; Melting Bullion;
Assaying Bullion; Humid Assay of Silver; Gay Lussac's
Method; Volhart's Method; Manipulation; Lead Ores; Cop-
per Ores; Tin Ores; Mercury Ores; Zinc Ores; Nickel
and Cobalt; Ochromium; Blamuth; Arsenic; Antimony; Sulphur;
Salt; Note.

One of the methods given for the Assay of Copper is new
original and exact, as is also one of the processes for Zinc.
The book contains 161 pages with illustrations, and is
strongly bound in cloth. Much of the original text is re-
placed by new matter.

Price, postpaid, \$1.75. Sold by DEWEY PUBLISHING
CO., Publishers No. 220 Market St., San Francisco.

ard Illustrated Weekly published at \$3 a year by DEWEY
UBLISHING CO., 220 Market St., San Francisco, CAL.

Useful Information.

The De La Bastie Method of Hardening Glassware.

The recent expiration of the patent covering the De La Bastie process for hardening and tempering glass will perhaps justify a reminiscence of the interest that was excited by the invention at the time of its first announcement, says the *American Manufacturer*. In 1874 there appeared in several German journals an account of a new method of hardening and tempering glass, the invention of Mons. A. De La Bastie, of Richmond, France. The account went on to describe the properties of this glass as sufficiently remarkable to justify the belief that a complete revolution in the industry was to be expected and glass was no longer to be synonymous with brittleness. No such marvelous results have been attained, but the process has some features which have kept it alive up to this date, and now that the barrier of this patent law has been removed, will doubtless lead to its further introduction in certain branches of the trade. The early tests of the samples which had been subjected to the treatment discovered by M. De La Bastie were such as would seem to justify the extravagant promises made for it at the time. The tests were made before a committee of three, delegated by the "Society of Glass Industry" of Germany, and afterward repeated before a meeting of the society. A comparative test, in which a sheet of ordinary glass about 5x8 inches in size and one-eighth inch thick, supported in a horizontal position in a loose wooden frame, was repeatedly broken by a leaden weight falling from a height of 20 inches, showed in a remarkable way the superior strength of the prepared glass, of which a similar sheet, similarly placed, withstood the blow of the weight falling from a height of more than 14 feet and broke only after repeated trials. Watch glasses of the "elastic" glass, as it was then called, were thrown up to the ceiling of the room, which was 14 feet high, and allowed to fall on the wooden floor, remaining unbroken through several repetitions of this same test. The articles when thrown to the floor vibrated as though made of metal, and rang with a distinctly metallic tone, but when finally broken, they flew into a thousand pieces. The same remarkable qualities were displayed by the articles when subjected to severe changes of temperature. Samples were heated to a low red heat, and were plunged into cold water without cracking them. The effect of these tests on the society before which they were made was that they at once entered into negotiations for the purchase of the patent for Germany. These negotiations were, however, broken off by the appearance of several other inventors, all of whom claimed to have discovered a process that would produce the same result.

The method employed by M. De La Bastie, as far as is known, consists in the sudden immersion of the article to be hardened, while heated to redness, in a bath consisting of oil, resin, and other similar substances, heated to about 570° F., and thus allowing the bath and the objects to be tempered to cool slowly together. The bottom of the vessel containing the heated bath is covered with a layer of sand, or a wire netting is stretched above it, to guard against breakage of the ware as it is plunged in, or the dipping is done by means of a wire tray filled with ware, the whole being immersed and withdrawn when the process is finished. The original glass, as made by De La Bastie, was of ordinary composition, being a soft alkaline glass containing 68 per cent silica, 10 per cent lime, 17 per cent alkali, 2 per cent alumina, and 3 per cent coloring matter. The specific gravity was 2.52, this latter property, it was understood, being somewhat increased by the hardening process. The principal difficulties encountered in the production of glassware by this process seem to have arisen from the behavior of the glass when immersed in the bath, and the difficulty in cutting or working the finished product. The first of these difficulties has led to the gradual abandonment of the manufacture of all articles whose shape does not permit of their being immersed in such a way that the liquid shall reach both sides at once, and which show marked irregularities in thickness. The second objection has resulted in shutting off of the manufacture of window or sheet glass by this method, since the finished product could not be cut into suitable sizes by any practical method, the diamond having no effect upon its surface. The only articles made to any extent by this process in this country are lamp chimneys, the peculiar shape of which is specially adapted to the requirements. The factory of E. D. La Chapelle & Co., in Ottawa,

Ill., has been engaged in this branch for some years, and is doing a good business. Their success in this line would go to show that the process can be made profitable under certain conditions, and now that the method is free to all, we may look for a further extension in its application. In the as yet undeveloped chemical ware branch, in the manufacture of glass tubing, and in the production of a window and mirror glass that is invulnerable to the ordinary misfortunes of its kind, we may still look for the previously enumerated difficulties to be overcome and an improvement in their intrinsic value to be made.

Diphtheria.

Concerning the management of a case of diphtheria, so far as that may fall within the domain of the parents, the following few rules, while not incorporating all, are still the most important for preventing the spread of this dreadful disease, and my earnest advice to every mother is to study them carefully, and preserve them for future reference.

First, strips of linen or cotton fabric, about eight inches wide, folded several times, and long enough to reach from ear to ear, should be wrung out of ice water (if in winter) and if in summer put directly upon ice, and then applied externally to the throat, and as fast as one cloth gets warm another should be ready to take its place. If the child complains of being cold, its feet and hands should be bathed in as hot water as it can stand. When the child is very young, it may be readily ascertained if it be cold or not by feeling its hands and head. Under no circumstances should hot applications be made to the throat. If the child is old enough it may be given broken ice to suck constantly, even if the water is spit out. The cold applications inhibit the growth of the microbes. The patient's hands should be washed frequently—and here let me say so should those of attendants—and the vessel used for the purpose should not be used for any one else. The patient's clothing needs protection in front. This may be done by pinning back of the neck a large piece of linen or cotton fabric, which will cover the whole front of the child and reach as far as the knees. A material should be used which can easily be boiled or burned when soiled. The little patient, if old enough, will want to spit, and for a spittoon a small wooden box with an inch of sawdust on the bottom is capital. Fresh sawdust should be supplied at least once a day—three times a day would be better—and that which has been used should be emptied upon a good, hot fire, and thus burned at the time the change is made. If there are any flies about, the box should be kept covered, and, as a matter of course, only uncovered when the patient desires to spit; otherwise, the flies alighting upon the spittle would carry the germs of the disease with them, and then alighting upon the family's food and drink, necessarily infect them, and thus indirectly infect the whole family. This is by no means chimerical, but a well-established fact.

All clothing and bed clothing that come in contact with a diphtheria patient contain the germs of the disease. For this reason all such clothing should be disinfected, and aired or washed before it is used again.

What is said of diphtheria is also true of scarlet fever and measles. The contagion of these diseases is in proportion to the severity of the case from which it comes. The less care given to ventilation and general cleanliness, the more active does the contagion become; but the contagion from a very mild case may cause very severe and fatal cases.

Both diphtheria and scarlet fever may be caused by milk poisoned with the germs of these diseases. There are on record at least 14 epidemics of diphtheria caused by milk.

In only one of these epidemics did any of the attendants about the dairies have diphtheria before the disease broke out among the customers. In one instance it broke out among the dairy hands and the customers at the same time. In five of these epidemics the dairies were in very unsanitary conditions; untrapped or open drains allowed noxious gases to reach the milk and milk pans. In this way a small amount of the contagion got into the milk and developed so rapidly as to infect a great many people.—*Half's Journal of Health*.

HOW TO SELECT ROPE.—A German paper, in an article on the methods of rope manufacture from hemp and the determination of the different qualities and the probable strength from the appearance, lays down the following rules: A good hemp rope is hard but pliant, yellowish and greenish gray in color, with a certain silver or

pearly luster. A dark or blackish color indicates that the hemp has suffered from fermentation in the process of curing, and brown spots show that the rope was spun while the fibers were damp, and is consequently weak and soft in those places. Again, sometimes rope is made with inferior hemp, on the inside, covered with yarns of good material—a fraud, however, which may be detected by dissecting a portion of the rope, or in practical hands by its behavior in use; other inferior ropes are made with short fibers, or with strands of unequal strength or unevenly spun—the rope in the first case appearing woolly, on account of the number of ends of fiber projecting, and, in the latter case the irregularity of manufacture is evident on inspection by any good judge.

GLYCERINE is one of those substances that always seem to be lending themselves to new and unsuspected applications. It is found that the freezing of water in the hydraulic machinery—a very serious source of trouble in the winter months—is extremely prevented by the simple experiment of mixing a small percentage of glycerine with the water in the pumps. This precaution is now taken in the operation of the hydraulic jack on all ships in the English navy. Glycerine appears to be just as useful in maintaining the efficiency of the human machinery, for it is recommended as a cure for indigestion. A small teaspoonful should be mixed in half a wineglassful of water and taken with or immediately after each meal until the trouble is past, which, in an ordinary case, will be in two or three days' time, and in an obstinate one probably from 10 to 15 days. The treatment will have to be renewed if the indigestion manifests itself again.—*Ex*.

Electricity.

Electricity in the Navy.

Warships, like other large steamers, are being daily transformed into regular factories and machine shops; the sailor now requires a knowledge of engineering as well as seamanship, as he holds in his hand the various appliances which serve to propel and guide the gigantic structure under his control. Electricity, that great source of energy, which can become at will a source of power, light, heat or chemical action, was destined to find numerous applications in the navy, and electric applications on ships are becoming more common every day.

The first use for which electricity was employed in the navy was for exploding torpedoes at a distance, says *Invention*. In consequence of this employment of electricity, the two words torpedo and electricity have become, as it were, almost inseparable.

It is not very long since the charges of powder serving to project self-acting torpedoes from the tubes were fired by means of electric friction tubes, with quite a complication of batteries, commutators and wires, when probably a simple tube-lanyard would have answered the purpose better, the operator in most cases being quite near to the tube.

Electricity has also been recommended and used for firing heavy guns, but claimed advantages should not outweigh the question of inconvenience, for mechanical firing is sometimes more simple and reliable. At the present day, moreover, there is a tendency to recognize the uses of electricity only where of unmistakable utility. It may happen, for example, that the commander of a ship or torpedo officer finds it necessary to fire the broadside of his guns or the locomotive torpedo contained in this or that tube, the training of the pieces having been previously executed, simultaneous firing or the propulsion of the torpedo at the proper moment can undoubtedly be advantageously effected by means of electricity.

The second application of the electric current in the navy was for the transmission of orders to a distance. Whoever has had an occasion or opportunity to witness a sham fight on board a ship of war, or the maneuvering of the machinery or various appliances employed for training and charging heavy pieces of artillery, can form some idea of the difficulty of receiving and transmitting orders on board ship.

Speaking trumpets and, in fact, all the phonic appliances, without excepting the telephones, are, on board, imperfect instruments, for if they more or less answer at the anchorage and when there is not too much vibration, they may become quite useless in the midst of heavy fire. Acoustic pipes, in which there must be numerous bends, often get filled with water; as for telephones, the great vibrations resulting from the firing of the guns, and the changes

of temperature, make them unreliable. Mechanical transmissions are also, perhaps, less practicable on account of the angles and gearing, etc., requisite, owing to the nature of the places and bulkheads crossed; the chances of error and cost of installation are consequently great. The future seems likely to suggest the extended employment of electro-mechanical transmitters, and many are already in use.

The introduction of dynamos soon brought about the installation of generators and powerful arc lamps for the purpose of reconnoitering the enemy at a distance, etc., or the navigation of passages; large ships sailing by night from Port Said to Suez were thus enabled to reduce the time of their passage in the canal by one-half. The incandescent lamp and the construction of dynamos with constant potentials have made the electric lighting of ships really practical. Neatness and safety from fire, the great economy resulting, together with the advantage of not vitiating the air, so difficultly renewed in the lower parts of a ship, and in addition to all this the greater lighting power, distributed as required over the least accessible places, are all good qualities which advocated the introduction and development of electricity into the navy. For the last five or six years, war and mercantile vessels have been largely supplied with electrical apparatus.

The facility with which incandescent lamps can be extinguished or lit from a distance naturally led to their employment for night signals, based upon the number, color or duration of the flashes, or the extinction of lamps placed in lanterns in the masts.

On ships of to-day all the parts below water (the largest in bulk and often the most important) are inaccessible to daylight; their lighting, therefore, must be permanent, and the engines must be run, without stoppage, day and night; yet nothing need prevent utilizing part of the current produced to work small motors like lathes, hoists, ventilators, etc.

At the present time they go even further, and holdy attempt transportation and distribution of power by electricity. Endeavors are made to substitute suitably contrived electric motors for the heavy hydraulic machines now employed for the maneuvering of big guns. The day does not seem far distant when there will be a central generating station provided for distributing light and power over ships. Later, perhaps, heat may be similarly transmitted.

Fault Indicator.

An instrument for automatically indicating the location of a fault on underground conductors has been in use on a very large network in Berlin for over a year, and it appears to have met with success. These indicators sound an alarm at the station the moment a fault is developed and indicate the locality. For this purpose the usual pressure wires are used which are so connected that a certain voltage exists between the copper conductor and the neighboring pressure wire; when a cable is damaged, the short circuit which then occurs between the pressure wire and the copper conductor produces a change in the voltage existing between them, which in turn actuates a relay and an alarm at the station without necessarily preventing the pressure wire from serving its purpose for indicating the pressure; the relay actuates an annunciator which indicates the district, each district comprising about a square. Besides this there are ground detectors at the station which show the condition of the insulation not only of the whole network, but of every single district. The system is based on the fact that the largest part of the loss of potential between the two points connected to earth is at those points, only a small portion being due to the resistance of the earth between the points. The conductors are therefore made to indicate the potential of the earth in the various districts. By means of single relays and simple voltmeter measurements, the locality of the fault is determined at the station. The sensitiveness can be made as great as is desired; the relays, for instance, can be made to operate with one-quarter of a volt or one volt, depending upon whether poor or good ground connections are to be indicated. A somewhat lengthy description of this system may be found in a paper by Dr. Kallmann, in the *Elek. Zeitschrift*, No. 11. The system is one devised by the Allgemeine Elektrizitäts-Gesellschaft.

A lengthy discussion of this paper is contained in the *Elek. Zeitschrift*, April 28th, the greater part of which, however, is devoted to the influence of earthed lighting circuits on telephone lines. The author explains a portion of his system by the aid of a diagram representing an actual case. His system seems to be of considerable impor-

tance, and is well worth the attention of central station engineers. Some of the remarks of Dr. Froelich are of interest. He compares it with his own (complicated) system and states that the former is not applicable if the faults are in the house circuits, where most of them occur. This, however, Dr. Kallmann denies, saying that he has applied it in numerous such cases. Both agree that grounding the neutral wire of a three-wire system diminishes materially the disturbing influence on neighboring telegraph and telephone lines.—Electrical World.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower Engine and 45-horsepower Boiler with Ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. OULLEST, 1914 Stockton St., San Francisco.

20-Stamp Mill for Sale.

In Southern California, a 20-stamp Old Quartz Mill, with engine, boiler, self-feeders, rock-breaker, etc. As the premises are adjacent to Railroad, the Mill could be conveniently removed. Can be had at low price for cash. Address "Quartz Mill," care Mining and Scientific Press, San Francisco.

THE CHRISTIAN ENDEAVOR EXCURSION To the World's Fair!

Will leave on Tuesday, June 20th, under the management of the "Young People's" Society of Christian Endeavor, via Salt Lake, Manitou (Pike's Peak), and Denver. Special features as to stopovers and accommodations! Both Palace and Tourist Sleepers! Secure an itinerary of the trip. W. A. BISSELL, O. P. A., 650 Market Street, (Chronicle Building), San Francisco, Cal.

METALLURGICAL CHEMIST.

I am desirous of erecting or superintending a large **CYANIDE LEACHING PLANT** for Gold Ores or Tailings. Thirty years practical experience in Leaching. For the past two years in Cyanide Leaching exclusively. Address "METALLURIST," This Office.

WHO PAY TOLL?

Mill Owners Who Don't

USE THE CELEBRATED

BRYAN ROLLER QUARTZ MILLS.

HOW?

BECAUSE it is the simplest Roller Mill made, therefore IT SAVES IN RUNNING EXPENSES.

BECAUSE It is the only Roller Mill made in which oil is prevented from dropping into the pulp (oil makes it impossible for the quicksilver to amalgamate with the gold), therefore IT SAVES THE GOLD FROM GOING INTO THE TAILINGS.

BECAUSE—well, there are too many ways of paying toll, and besides it would only weary you to read of them.

All who use this mill can testify to its merits. We want to sell you a mill, so write to us for testimonials and particulars, or to some of the users—it makes no difference.

SOME OF THE USERS:

THE CANDELARIA CONSOLIDATED MINING CO., San Dimas, Durango, Mexico..... 4 mills.
THE TABOR MINE AND MILLING CO., Oñadalajara, Mexico..... 4 mills.
ELKHORN MINING CO., Baker City, Oregon..... 2 mills.
PHOENIX MINING CO., Oroville, Cal..... 1 mill.
GOOD HOPE CONSOLIDATED MINING CO., San Diego, Cal..... 1 mill.
AND MANY MINES ALL OVER THE WORLD, whose addresses we will gladly send you on application.

DEWEY & CO.'S

Scientific Press

Patent Agency.

ESTABLISHED 1863.

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 220 Market St., S. F.

FRUE ORE CONCENTRATOR

OVER 3200 IN ACTUAL USE.

Manufactured under Patents of April 27, 1880; September 18, 1883; July 24, 1888; and March 31, 1891.

Price of 4-foot wide Plain Belt Frue Vanner.....\$550, f. o. b.

 " 6-foot " Plain Belt Frue Vanner.....800, f. o. b.

GLADSTONE MINING COMPANY, C. J. Clark, M. E. Gen'l. Supt. FRENCH GULCH, Calaveras Co., Cal., Dec 12, 1891.
 MESSRS. ADAMS & CARTER, San Francisco, Cal.—DEAR SIR: During my experience in mining and milling, I have used twenty-four of your four-foot Frue Vanners on different kinds of ore, both gold and silver. I have made competitive tests against them with other widely puffed-up concentrators and have always found the Frue in first place. When I built this mill (40 stamps), I determined to put in six-foot Frues in order to save space and machinery. I am now running four of your six-foot machines and they have been going for twelve months. They are taking the pulp from 20 stamps, crushing a minimum of fifty tons per day, and do better work than the four-foot tables. They require no more attention than a four-foot table and handle at least twice the quantity of ore. I have run them up to 80 tons per day and could not see that they were crowded. They stop and start as easily as the smaller tables and have the advantage of double capacity with the same bearings and wearing parts, requiring no more oil, and no more wear and tear than the smaller tables. My repair account for the past six months has been too small to mention. In order to give an idea of the work they are doing here I will state that the ore has varied monthly from \$5 to \$20 per ton and the tailings from nothing to 60 cts. per ton. I will conclude by saying that I cannot endorse the six-foot Frue Vanner too highly, and it is the only table that I would have in my mill.

O. J. CLARK, Gen'l Supt.

Mining Summary.

The following is mostly condensed from journals published to the interior, to proximity to the mines mentioned.

CALIFORNIA.

Amador.

WOODBRIDGE.—Amador Dispatch, June 10: The Woodbridge mine near Clinton is being vigorously prospected, and every indication looks favorably for a valuable mine. The tunnel has now reached the ledge, and they are now running the tunnel along the hanging wall of the ledge, taking out about four feet of rock which is of good quality. They have not yet crosscutted the ledge, and consequently they do not yet know exactly how thick it is. The tunnel has already been run along the ledge about 60 feet, and will be run 40 feet farther on the present contract.

WATER.—Amador Ledger, June 9: The Baldwin has been blowing the whistle now for several days. They have a heavy body of water in the shaft, and it will be several days before they get it out so that they can commence work on the orebody. Mr. Knight's hydraulic pump at the Bay State seems now to be giving satisfaction. It is throwing a constant stream of 18 miners' inches of water, and with what they take out with the water tub, is lowering the water steadily, and in a few days, when they open the face of the tunnel, I have no doubt the water will drain to one-half its present depth. They had the same experience in the Onelda mine at one time; the water would break in in heavy streams from the face, filling everything directly, and in some instances it would take three days to drain these subterranean reservoirs. The Pioneer people are putting on quite a number of men, which induces me to believe that they are satisfied with the developments. The rock in the Onelda tunnel has become softer and consequently the work of driving the tunnel will be much accelerated; and, if it keeps as it is now, it will only be a short time until they strike the ledge. I was over last week and examined the property, and my judgment is that they are going to have a fine property here. When they get their tunnel in, they will have backs of some three hundred feet. The Plymouth or Middle Fork ditch runs right by the mouth of the tunnel, and the mountain breaks off so abruptly that it gives them in a few hundred feet plenty of fall to run any kind of machinery, thus giving them a splendid mill-site below the mine into which the ore can be run through chutes. The company is composed of six business men of San Francisco. Mr. Wray, the president, informed me that there was no stock for sale. If the development proved good, they would own it all; and, if not, they were willing to lose.

KEYSTONE VS. SPRING HILL.—The Keystone Mining Co. has sued the South Spring Hill Mining Co. for \$200,000 damages for ore extracted through the latter's shaft from the property of the former. The Keystone asks for the above damages and a perpetual injunction. Lynch & Rust are attorneys for the plaintiffs.

WALLACE VS. AMADOR GOLD MINE.—In Dept. 3 of the Superior Court of the city and county of San Francisco, judgment has been rendered against the Amador gold mine for \$149,259.35, with legal interests and costs, in favor of Wm. A. Wallace. A copy of the judgment was filed in the Recorder's office of Amador county the 7th inst.

Butte.

FROM OROVILLE.—Plumas National Bulletin, June 6: E. A. Hallstead, proprietor of the Oroville Stage Line, came up on Friday last and returned Monday. The town of Oroville is in a prosperous condition, and the mining outlook for Butte county, particularly in the line of quartz, was never better. Capitalists are reaching out for gold mines more eagerly than for many years past. Several big quartz propositions have been developed in Butte recently, and they are proving a success. Numerous are the inquiries also about Plumas mines. Mr. Hallstead is confident that a new era for gold mining is at hand.

Calaveras.

GYPSUM.—Mokelumne Hill Chronicle, June 10: We have been informed by Mr. E. H. Davison, who is superintending operations at the Gypsum mine, which is located about six miles from this place, that he now has out over ten tons and all sacked ready for shipment to San Francisco. The Gypsum is to be used in the manufacture of carbonic gas in one of the principal soda works in the city. Mr. Davison will have a machine for grinding the gypsum to a powder in a short time, when it is intended to ship it in barrels—about 250 pounds to the barrel. Gypsum is worth \$20 per ton in San Francisco, and as the mine in question contains an unlimited quantity, there is every reason to believe that it will be a permanent and paying investment, and also give employment to quite a number of men.

Del Norte.

BEACH SAND MINING.—Del Norte Record, June 10: The Beach Sand Iron Mining Company, below town, will soon be at work extracting magnetic iron from the sand. They have completed a substantial building, which is made "sand tight." Probably many people would like to learn of the process of extracting the iron, but that is a secret, well guarded. It is said that this plant is an experiment, but already the sand prospected shows that it will pay handsomely. The company has a lot of the finest machinery which must have cost considerable. The result of the new mining industry is awaited with great interest. Should it come up to the expectations of the parties interested, it will mean the erection here of a smelter, besides an increase of transportation facilities between here and San Francisco, also the employment of quite a number of men.

Inyo.

LEAD CANYON.—Inyo Register, June 8: Ex-Sheriff J. R. Eldred started for Lead Canyon this morning, accompanied by Mr. James Wright, an old and experienced lead prospector and miner. Mr. Eldred has some excellent prospects in this district. This mining belt is situated about 40 miles from Big Pine, in a southeasterly direction, approachable from the bamlet via Devil's Lute, Marble canyon and Wacoba Springs, points on the Saline

valley borax road. Some good lead ore has been shipped from this section to the Selby Works of San Francisco. The district will receive considerable attention during the present season. Mr. Dailey, of Fish Springs, made a cleanup of \$700 from a 10-ton run of gold ore last week. Tracy & Cunha will commence crushing rock the present week.

Lassen.

A PLACER MINE.—Amedee Geyser, June 6: Some time ago Messrs. John Christie, Bob Squires, Wade Lawson and Wellington Adams took up a claim in Last Chance, about eight miles from Milford. Very little had been accomplished, however, until recently, when the first strike was made. Mr. Sifford exhibited specimens of flake gold taken from the sluice-box while the water was still running, the largest of which is worth 25 cents. That large results may confidently be expected is apparent from the fact that nine cubic feet of earth yielded \$15 worth of the precious metal.

Nevada.

QUARTZ.—Nevada City Herald, June 6: The Live Oak quartz mine, situated near the Delhi, is quite likely to close down pending the settlement of certain difficulties between its owners. The mine is really a big one and has been sufficiently developed to show its value. Two tunnels have been run into this ground, one 100 and the other 120 feet in length, and a large amount of quartz has been taken out and piled up. Conservative miners estimate that there are 10,000 tons of ore in sight, the formation being a large one, and it is said that the ore will pay \$8.50 per ton. It is hoped that some arrangements may be made by which the mine may be worked on a large scale, as it would live up the whole ridge. The Union mine at Relief Hill is looking well, and continues to pay its owners and furnish employment for quite a force of men. A new tunnel is to be run into this ground. At the Derbec work continues as before. Negotiations are said to be pending with Mrs. De Noon, who owns the ground to the east, and if this ground is secured the mine's existence may be prolonged for years to come. Some Live Oak men, while making a trail from their cabins down to the mine recently, ran across the upper end of the Grizzly Ridge Company's ground and uncovered a very good ledge about two feet thick. The Grizzly Ridge has good ore and lots of it. Williams & Co. continue to work their claim in Grizzly canyon and have good rock.

PARNELL MINE.—Grass Valley Telegraph, June 10: The Stewart Parnell mine is situated but a little way from the South Idaho, and the ledge is a parallel one from that most excellent prospect. The mine is owned by Mr. Hogan and a company of miners, and they all have the utmost confidence in the affair. But little work has so far been done on the property, the shaft having just been started. There is a four-foot ledge now in sight, and many pieces broken from the vein show gold. What that country out there will do, no man can tell, as there are innumerable ledges and gold can be found in all of them.

Plumas.

IMPORTANT DEVELOPMENT.—National Bulletin, June 6: The Mercury quartz mine, owned by Lee, Richards & Blakesley, pierces the hill north of Western Ravine beyond Emigrant Hill, and is in the vicinity where existed fabulously rich placer and drift mines in the early days of gold-mining in Plumas, where it was no uncommon thing to secure nuggets whose value ranged up into many hundreds of dollars. The Mercury was discovered about a year ago by Johnny Richards, an old-time prospector. On top of the hill a shaft has been sunk 40 feet. Here the ledge is about 12 feet wide and situated between well-defined slate walls. The ore vein has been developed at different points from this shaft to the bottom of Western Ravine, which cuts it. Evidently the large ore body goes down. The chimney developed at the shaft is of a soft, decomposed nature and shows big prospects, indicating that the ore will yield, by the free-milling process, from \$6 to \$20 per ton. By a short tunnel from the Newtown Flat side, the lode can be tapped at a depth of probably 300 feet. With a 10-stamp mill erected near by, here is a mining proposition worthy the attention of capital. It is in a country that has produced lots of money, prospects well itself, is easy of access and can be worked very cheaply.

FROM RICH GULCH.—A. D. Hallstead was up from Rich Gulch Saturday. He reports the outlook for the Hallstead mine to be very bright. Recent developments inspire greater confidence in the value of this property. The tunnel began several months since is being pushed ahead, and it is now in good ore. The owners think they have about reached the large chimney whose ore near the surface prospected well. The vein matter is now getting softer. That there are five large chimneys on the locations, Mr. Hallstead says the work done thus far fully demonstrates.

BUCK'S RANCH AND GRANITE BASIN.—Reports come to us that the Granite Basin and Buck's Ranch country are full of prospectors, mainly from abroad, and that indications point to lively times in that country during the coming summer, with reference to both quartz and gravel-mining interests. We are glad to hear of this, for certainly there is a large and important field there for discovery and development. The extremely rich body of ore uncovered by See & Jolly last fall demonstrates that very superior quartz veins exist at Granite Basin. The country is practically unexplored and is in need of experienced gold-bunters to find more mines and of capital to open up those already found.

GENESEE MINES.—National Bulletin, June 6: From H. C. Flournoy, who was in Quincy, Monday, we learn that the future of Genesee valley is bright. This valley is conceded to be one of the most charming spots in Plumas. It is a narrow strip, the rugged mountains on either side rising in their grandeur to a height that is almost dizzy. Not only in point of scenic beauty is it interesting, but it has attracted attention among scientific men because of its fossils. Copper, gold, silver and iron ores abound. During the past 35 years, more or less mining has been done in that region and much gold has been extracted. A large part of the ores carry gold, silver and copper, and is of a rebellious nature, a large percentage of the gold even being lost by the free-milling process. There is not the case, however, with all the mines there. During the past month several mining men and representatives of capital have visited Genesee for the purpose of looking at the mining properties

there, with a view of investing. A short time since Messrs. Gullic and Cloud, of Illinois, and Messrs. Hook and Roberson, of Genesee and Backwith, respectively, located a quartz claim about a mile north of the Flournoy ranch. The vein is about three feet wide and carries gold, silver and copper. It can be traced nearly three miles. The locators have begun development work and will continue it during the summer. A Chicago company has been prospecting the old Cooper mine. Their work thus far is reported to be quite satisfactory, the ore on top proving very good. Further prospecting will be done, and if the ore continues good it is stated that the capitalists will erect large reduction works to reduce the rebellious ores and save all the precious metals. The most notable development made in that section lately is that accomplished by George Brown. He is interested in the Green Ledge. About a quarter of a mile above and entirely separate from the Green Ledge, has been exposed to view a large body of quartz which was supposed to be worthless. Mr. Brown began work on it, however, and by running a short tunnel has reached a four-foot ledge of high-grade ore, entirely different in character from that of the Green Ledge below. The owner is extracting some of the quartz and hauling it to an arrastre to test it as well as he can by that process. By means of a tunnel this body of ore can be opened up to a depth of fully 1000 feet and delivered at a point where a mill run by water-power could be erected and operated cheaply. The owners of the Cosmopolitan have resumed the work of driving their tunnel ahead to tap the Mammoth ore vein. John Sobrero, above the Genesee mine, has a small ledge that is considered very rich, though, as yet, it is developed to a limited extent only. Lately some English capitalists were up to see the Cascade gravel mine, on Grizzly creek, owned and operated by P. R. Walsh, of Vallejo. Should a sale be effected, the property will be worked on a large scale. A Dragovich has gone up to the Lucky S mine to begin work. He expects to put in needed machinery and prosecute work actively.

Shasta.

LOCAL MINING NOTES.—Shasta Courier, June 10: With two milling plants running at South Fork, and another one in process of construction, that district ought to come to the front as one of the leading mining districts of northern California. Charles Albino and Fred Forslund have been making some repairs on the old Sam Brumfield ditch from Flat creek, owned now by the Calumet Co. That company also owns a couple of promising mining properties at Flat creek. The old Bob Small and Farmer mine now owned by Vet Hull and Wm. M. Murray, of Shasta, and B. Conroy, of Redding, is showing up in a most flattering manner. Mining men pronounce it to be one of the most promising properties in this section. The ledge is five feet wide on top, and justifies everything that has been said in regard to its richness. Murray and young Conroy are running a tunnel in the hill, being in about 25 feet, and expect to strike the ledge soon. The mine is located near the divide between Iron Mountain and Whiskytown, and is about four miles from Shasta.

Sierra.

COMET.—Mt. Messenger, June 10: We understand that parties will be here from the lower country shortly to undertake the development of the Comet Consolidated quartz property, in Jim Crow canyon. It will be but a very short time before others of our many valuable quartz deposits in this vicinity will be bonded or leased to those who can afford to develop them, and then prosperity will be bound to follow. Sierra county's quartz ledges are comparatively unexplored, and contain many thousands of dollars. Work at the Maple Grove drift mine, Alleghany, has been suspended, but will be resumed next fall. Gravel at the Excelsior drift mine at Cedar Grove near St. Louis, northern Sierra, is paying \$4.50 a carload. This mine promises to become one of the best in the county, as it undoubtedly has the upper part of the noted Howland Flat channel.

Siskiyou.

CLEAN-UP.—Yreka Journal, June 12: Mr. Rider, of Humburg, spent a few days in Yreka last week, and says they have an abundance of water and have just commenced to clean up after five months' sluicing, and anticipate a fine clean-up. The Lang Brothers, of Humburg, were in town last week. They have had the best supply of water and this has been the best year for mining that there has been in this county for ten years. They have piped off a big piece of ground, and, as they have an extensive claim, they will certainly realize a fine clean-up. Clark & Wheeler have had five tons of ore from their mine on Middle Fork of Humburg crushed at McCook's mill as a test, and the result was highly gratifying. There has been a number of mining men in Yreka, from the lower cities, during the last week, looking after some of Siskiyou's valuable mines with a view of investing. They went to Humburg and other places to investigate for themselves the buried treasure.

Trinity.

LOOKING WELL.—Journal, June 10: We have been informed that the outlook of the Enterprise Company at East Fork is very bright, more so than it has been for some time. The mill is and has been running several weeks on ore taken from the Lone Jack location, and the plates show up very encouragingly.

Tuolumne.

THE KINCAID MINE.—Independent, June 10: Situated in Kincaid's Flat is a mine known as the Kincaid mine. It is of gravel formation and worked by a hydraulic monitor, with a pressure of about 200 feet fall, coming from the adjoining hills, through a 12-inch pipe. The hole, or mine itself, is about 60 feet in depth by 300 in length and 100 feet wide. A constant flow of water from the monitor is kept on the walls being worked, and every other day the full force of the stream is turned on. The force of this stream is something wonderful. The slightest touch turns it in its course, while wherever the stream strikes, it tears everything before it, turning and upturning huge boulders as if they were mere pebbles. The flume conveying this water, after it has performed its duty, runs through a tunnel in the mountain, which is about a mile in length, and flows into Sullivan's creek. For years past this mine has been worked in this manner, yielding to its owners a large income.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—Virginia Chronicle, June 10: 1500 level.—The drift started west from the end of the southwest drift, 75 feet above the sill floor of this level, has been extended during the week 15 feet; total length 92 feet; ending in hard porphyry. From this west drift, at a point 30 feet in, a south drift has been run 30 feet in a quartz formation which assays from \$2 to \$3 per ton. 1650 level.—Have continued making necessary repairs to the drifts on the sill floor of this level and to extract some ore in working west from the old stopes, on the third floor, operating through the upraise, No. 6 carried up from the main northwest drift. Also from the old stopes in working north from the crosscut run west from the northwest drift. The crosscut run east from the drift run south from the end of crosscut run east from a point 60 feet up in the upraise which was started from the drift run west from these north workings, 27 feet above the sill floor of this level, has been advanced 32 feet; total length 55 feet, continuing in porphyry and quartz showing some value. Have continued to extract some ore of average quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. The drift running south from this winze at a point 52 feet down has been extended 20 feet; total length 60 feet; in a porphyry and quartz formation. Have extracted during the week from all parts of the mine 178 cars of ore about 175 tons, the average assay value of which per car sample was \$28.49 per ton.

OPHIR—1565 level.—The work of pumping out the water which was reported last week to be flowing into the crosscut run west from the bottom of the winze sunk 52 feet below the sill floor of this level having been suspended, the water there has risen 28 feet and become stationary in the winze 24 feet below the sill floor of this level. From the winze station on the sill floor of this level an east crosscut was started and has been advanced 21 feet in a formation of porphyry, clay and quartz, which carries a low assay value. Have continued the work of making the necessary repairs in the shaft, being joint work with the Mexican company.

MEXICAN.—On the 1565 level.—West crosscut No. 2 from the north drift from east crosscut from the bottom of the winze, sunk from the 1465 level down to this level near the south boundary, has been extended 14 feet; total length 295 feet; continuing in a very hard porphyry formation. Have continued the work of making the necessary repairs in the shaft, being joint work with the Ophir company.

UTAH—340 level.—A north drift from the west crosscut No. 3, at a point 100 feet in from its mouth, has been started and advanced 7 feet. No work has been done in the face of west crosscut No. 3 during the past week, as the flow of water is too strong to work to advantage. Have repaired the south drift from the end of the west crosscut from main shaft.

SIERRA NEVADA.—The intermediate tunnel on Cedar Hill has been advanced during the week 16 feet, making the total length 386 feet; the face is in porphyry, clay and quartz. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 19 feet, making the total distance west of the joint shaft 3247 feet; the face is in hard porphyry, and streaks of clay and quartz.

UNION SHAFT.—The joint Sierra Nevada and Union west drift, 900 level has been advanced the past week 19 feet, making the total distance west of the shaft 3247 feet; the face is in porphyry and streaks of clay and quartz.

ANDES.—On 420 level have been repairing main north drift. Have started a south drift from east crosscut No. 1 north, and advanced it 12 feet. This drift is all in quartz.

GOULD & CURRY—200 level.—West crosscut No. 5, started in northwest drift, 432 feet from main west drift, has been advanced 10 feet; total length 503 feet; passing through hard porphyry. Suro tunnel level.—During the past week we have been laying a switch and have started jointly with the Best & Belcher company, at a point in the northeast drift, at a point 122 feet from the main north drift, an east crosscut (No. 1) and advanced same 8 feet; face in porphyry and small stringers of quartz.

BEST & BELCHER—200 level.—West crosscut No. 2, started in northwest drift, 230 feet from our south line, has been advanced 13 feet, passing through quartz; total length 143 feet. 900 level.—Work has been discontinued in west crosscut No. 4. We have resumed work in southwest drift 112 feet from crosscut No. 3, and advanced same 15 feet through hard porphyry, total length 129 feet. Suro tunnel level.—During the past week we have been laying a switch and have started jointly with the Gould & Curry company at a point in northeast drift 122 feet from the main north drift, an east crosscut No. 1, and advanced same 8 feet; face in porphyry and small stringers of quartz.

HALE & NORCROSS.—1800 level.—We resumed work on Monday, the 5th inst., and carried up the upraise in west crosscut on our south boundary on this level 16 feet making total height 66 feet. The top of upraise continues in quartz. Main shaft.—We continue retimbering above the 1300 level, and are retimbering main incline where most needed. When the necessary preparations are completed we will begin work on the 900 level with a view to doing extensive prospecting in unexplored ground on that level.

CHOLAR.—We are making repairs on the 450 level, and making repairs to the north drift, 850 level. Have started a drift north from the east crosscut near the south line, 930 level, at a point 250 feet east of the footwall, which is now out 24 feet; face is in clay and porphyry.

WARD SHAFT.—Work during the week has been confined to lining up the shaft and making repairs to the donkey pump on the 1800 level.

BULLION.—Work at the Ward shaft during the past week has been confined to lining up the shaft and making repairs to the donkey pump on the 1800 station.

EXCHEQUER.—Work at the Ward shaft during the past week has been confined to lining up the shaft and making repairs to the donkey pump on the 1800 station.

ALPHA.—Work at the Ward shaft during the past week has been confined to lining up the shaft and making repairs to the donkey pump on the 1800 station.

POTOSI—The south drift, 35 feet west of the main shaft on the 550 level, is out 32 feet; face is in porphyry. The south drift 200 feet east of Potosi winze, 930 level, is out 32 feet; face shows five feet of fair milling ore. The north drift, opposite the last named drift, is out 110 feet; face shows from three to five feet of good ore. There are three feet of fair grade ore in the top of raise from north drift 930 level. The north raise, above the 1000 level is 134 feet on the slope; top shows seven feet of good ore. The south stope above the 1000 level, 120 feet south of top of raise from the 1100 level, is out 80 feet; face is in porphyry. Extracted and sent to the Nevada mill the past week 709 tons and 1250 pounds of ore from the 550, 930, 1000 and 1150 levels. Milled during the week 620 tons. On hand at mill 180 tons and 750 pounds. Average battery assays, \$28.14; average car sample assays, \$31.24; shipped to the U. S. Mint, Carson, 354 pounds crude bullion.

OCCIDENTAL—We are extracting ore of fair quality from the south drift, 650 level. The upraise from south drift, 650 level, started at a point 310 feet south of main winze, is up 11 feet; the top shows bunches of ore. Have stopped work on the 750 level for the present. No 3 crosscut from Zedig drift, Sutor tunnel level, has been extended 15 feet; face in quartz and porphyry.

KENTUCKY—Have stopped work on the 160 level and moved all the men to the 1100 level. On the 1100 level we have extended the main south drift a total distance of 45 feet, in ore of milling value. The raise near the north line is up 28 feet in ore of milling value. The joint east crosscut on the Jacket south line is in a total distance of 47 feet; face is in ore assaying \$26 per ton.

Central District.

NEW GOLD DISCOVERY.—*Silver State*, June 10: L. F. Dunn returned last night from a prospecting trip. After making several rich placer locations in the Humboldt range, he went over into Central district. There he discovered a gold ledge four feet in width, and as the miners say, it was "lousy with gold." It was found about 500 feet north of the northern boundary of the Blackbird and Fellows' claims, and lies between a slate and sienite formation. He says these other claims are spurs of his mine—that he has the mine of the district. Dunn and M. S. Bonfield are the locators. In early days it was thought that our mines of value were silver mines and little attention was paid to gold. But, from the valuable mines now being worked and new discoveries made in Central, Rebel Creek and Kennedy districts, it seems we have most valuable gold veins. Besides, hundreds of Chinamen and a great number of white men are taking out large quantities of gold from the many placer claims in this county. Dunn says the goldbugs cannot get the best of him, as inside of 12 months he will have more gold than any of them.

Eureka District.

ORE SHIPMENTS.—*Eureka Sentinel*, June 11: The Eureka and Palisade Railroad Company received during the month of May 2173 tons of ore from the mines of Eureka district for shipment to Salt Lake City, as follows: From the Diamond mine, 1144 tons; Eureka Con. Mine, 381 tons; Jackson mine, 174 tons; Richmond mine, 134 tons; Hamburg mine, 110 tons; Phenix mine, 61 tons; Dunderberg mine, 31 tons; Bullwhacker mine, 15 tons; Williamsburg mine, 15 tons; Delaware mine, 13 tons; R. J. & Co., 13 tons; Ethel mine, 11 tons, and Rescue mine, 11 tons. From Hamilton, White Pine county, from C. A. Mathewson, 18 tons; Tom Cornell, 45 tons, and Zanni Brothers, 50 tons. Total from White Pine, 113 tons.

Jefferson District.

DEVELOPING.—*Silver State*, June 10: Henry Hancock informs us that they had pleasant weather at Jefferson during the past month, and that the mine-owners are developing their mines in that district.

Kennedy District.

ORE SHIPMENT.—*Silver State*, June 8: Benton & Kennedy made a shipment of 45 tons of ore last evening to the Reno Reduction Works. The ore is from the Imperial mine, in Kennedy district, and is expected to average about \$80 per ton.

TO RENUE SOME ORE.—*Silver State*, June 9: Mr. Kennedy, the discoverer of the rich gold mining district in this county, which bears his name, is in Reno making arrangements to have 75 or 100 tons of ore worked at the Reno Reduction Works.

ORE SHIPMENT.—*Silver State*, June 13: E. S. Archer, agent of the Portland Smelting Works at Linnton, Oregon, yesterday made another shipment of 20 tons of ore from Kennedy district. Fifteen tons of the ore are from the Goldnote mine and five from a claim owned by A. Barrett.

Tuscarora District.

CAMP NOTES.—*Times-Review*, June 6: The De Frees mill, which was disabled for a few days, has been repaired and is running again. The Pondere ore shipped by A. A. Rose to Salt Lake for reduction, we understand, yielded beyond his most sanguine expectations. Leasers in the Navajo and the two Isles will ship their ore in a few days, as "the butcher, the baker and candlestick-maker" all "wanta da mun." Ore was struck in the Rubé Batters shaft on West avenue yesterday afternoon, but its extent and richness has not yet been ascertained. Ore stealing has been carried on with a pretty high hand of late. Some of the crooks have succeeded in getting safely away with their hoards; others are awaiting a favorable opportunity to skip out with their ill-gotten gains, and the companies are dead on their racket.

LOWER CALIFORNIA.

GOLD QUARTZ.—*S. F. Chronicle*, June 13: Among the arrivals from Santa Domingo, Manuela Lagoon, Lower California, this week, is John Cranz, who for four and a half years has been buried in the mountains of the peninsula while engaged in the cattle and mining business. Mr. Cranz says: "There are some marvelously rich gold quartz mines, known as the Calmali properties, developed by Emiliano Ybarra, 50 miles east of Santa Domingo, in the backbone of Lower California, and these have just been sold to a party of San Francisco capitalists. There is, I am informed, \$500,000 worth of mineral in sight, and I believe that in a couple of years there will be 10,000 people there. All the country about there is rich. It is a richer region than that about Grass Valley, if possible.

The purchasers are John D. McKee of Tallant's Bank, Mr. Cantrell of the National Iron Works, Mr. Schacht of Schacht, Lemcke & Steiner, the merchants of Drumm street and M. C. Rhodes, the engineer who reported on the mines. The amount paid is a secret, but was undoubtedly a big figure. The purchasers came up on the steamer Carlos Pacheco with me." Mr. Cranz says the purchasers of the mines will put on a force of 400 men and develop them rapidly. There are 16 claims and all show ore. The pay streak in some places is two feet thick. The footwall is granite and the hanging wall slate. Mr. Cranz is on his way to Europe, to be absent several months. He predicts that there will soon be great activity in gold mining in Lower California.

MEXICO.

NEW "DIGGINGS."—*Tombstone Epitaph*, June 10: Mr. Jas. T. Dryden, who came in yesterday from the new "diggings" below the line, is an old, experienced miner, having mined and prospected in Mexico and Arizona for the past 12 years. He says there is no doubt plenty of gold there, and it can be profitably worked. The diggings are some 30 or 40 miles below the line, and there are evidences of their having been worked many years ago, but the early workers had by no means got into the richest dirt. There are some 30 Mexicans there and 6 Americans, who are working the ground in a primitive way and are realizing from \$15 to \$20 a day each. Since work was begun, about three weeks ago, some \$10,000 have been taken out. Provisions are high-priced and scarce, and those contemplating the trip are advised to outfit themselves accordingly. Flour is worth \$16 a hundred; beans are a luxury and command 25 cents a pound, and hard to get at that price. As there is a mescal distillery about 20 miles distant, there is a sufficient quantity of that beverage to quench the thirst at 12½ cents a drink and the owner is coining money. Water is very scarce and has to be hauled eight or nine miles for drinking purposes. Mr. Dryden brought up several ounces of coarse gold with him, and those who saw it immediately became infected with the fever. Should more favorable reports of the new diggings be received, an exodus from Tombstone may be looked for. Mr. Dryden left early this morning for the diggings, and promises us a report in the near future.

MONTANA.

A TEST PLANT.—*Butte Inter-Mountain*, June 10: P. A. Largey, of this city, is making extensive preparations for the erection of a test plant near the Liquidator concentrator in Meaderville for the treatment of the vast quantity of tailings in that locality. During the past week J. M. Montgomery & Co., the machinists, have been engaged in fitting up a number of Chili mills for this purpose. These mills are being remodeled after the pattern of the Bryan mill and will be thoroughly tested. If the tests with this apparatus is not satisfactory, the Mc-Kim process will be given a trial. It is estimated there are nearly a million tons of tailings in the creek between the railroad bridge and the lower works of the Boston & Montana Company, and if this vast quantity can be worked at a profit, employment will be furnished to a great number of men.

THE ANSELMO.—The Anselmo mine, across Missoula gulch, has been closed down, the lessees being unable to make suitable arrangements with the owners, one of the conditions required by the latter being that the lessees should sink 250 feet during the next 12 months. During the past year the Anselmo has produced over \$30,000 worth of ore, much of this being obtained from the old workings abandoned by former lessees. Rich bunches of silver quartz were encountered near the surface, some of which assayed as high as 400 and 500 ounces to the ton.

THE NEVER SWEAT.—Sinking from the 700-foot level of the Never Sweat property was commenced last week and work will be prosecuted until the 800-foot level is reached. Two boilers of 75-horse power each were placed in position at this property during the week. The engine is being manufactured at an Eastern iron works and is not expected to arrive for some time. A temporary engine will, however, be used until the new one arrives.

THE BLUE JAY.—The work of developing the shaft at the Blue Jay is still in progress under the direction of the Butte & Boston officials. This property was worked by Dr. Whitford and others some four years ago. The Parrot workings traverse this property, and some three years ago the Parrot miners tapped the Blue Jay shaft, which at that time was full of water. The water went through the Parrot workings with such rapidity that several of the miners had narrow escapes from drowning. The Blue Jay ground is not considered by the Parrot miners to be a very promising field for mining operations. There is a six-foot ledge which assays well in iron, but shows very small quantities of copper and a great quantity of "black jack" in that locality.

THE ONEIDA.—The Oneida property, near the Silver Bow mill, will be in operation again next week, Messrs. Davis, Porter & Co. having secured a lease on the ground. This property was worked last year by F. A. Heinze, who spent some \$7000 in the work of development, but who abandoned it when he secured the lease on the Stella. T. M. Adams, the owner of the Oneida, has worked a few men this year, and recently encountered an 18-inch streak of copper ore which assayed about 10 per cent in copper and several ounces in silver.

LEXINGTON.—At the Lexington mine no work is being performed below the 800 level. Recently a number of miners secured a lease on the ground above the 400 level of this property. These lessees will work the old stopes and drifts, but will not be allowed to touch any virgin ground. The royalty will be graded according to the quality and amount of ore extracted. The lessees furnish all materials. The working of these old stopes will be an excellent thing for the mine, and will permit of the cleaning up of a great deal of ground, parts of which contain bunches of good mineral.

THE BELMONT.—The Butte & Boston people have decided to develop the Belmont mine, which is now being worked in a small way, and to this end a contract will be let shortly for the sinking of the shaft an additional 200 feet. The shaft is now developed to the depth of 225 feet. The Belmont is situated in the rich Ground Squirrel district and has produced some very rich ore during the period it was worked.

THE TRAMWAY.—The machinery has been placed in position at the Tramway, one of the Butte & Boston new properties, and next week the work of pumping out the water in the 250-foot shaft will be commenced. Just as soon as the shaft is cleared of water the company will renew the work of development, the first work contemplated being the sinking of the shaft to the 350-foot level.

PHILLIPSBURG MINES.—*Mail*: The development of the Royal gold property has again been resumed, and it is said that about a dozen men are employed there at present. The principal work will be in tunneling and crosscutting, with the probable addition of power drills to facilitate the work. Considerable ore is being taken out at present from the Two Per Cent property, near Tower, and the parties who now have it under lease are hopeful that the present showing will continue to improve, which, if it does, will afford them a good profit on their work. The Hope Company has purchased a new Sullivan diamond drill, and have begun prospecting with it on the hillside above the mouth of the Jubilee tunnel.

OREGON.

THE SPENCER.—*Ashland Tidings*, June 10: The Spencer mine, seven miles west of Coles, Cal., is one of the new mines in this region already opened and put upon the basis of paying property of established value. It was bought last year by Mr. Spencer of Portland, W. W. Walters, C. B. Kingsbury and Phillip Mullen of Ashland. Walters sold his one-sixth interest last fall to Mr. Kingsbury for \$5000, and now the mine is owned by Spencer, Mullen and Kingsbury, each having one-third. Their lode is a vein varying in thickness from 6 to 18 inches and shows paying prospects wherever tapped, from the surface to the bottom of their deepest shaft. The development consists of two tunnels, air shafts and a number of drifts from which ore has been taken for milling already done and yet to be done. The first tunnel tapped the ledge about 40 feet vertically from its surface croppings, and at this level drifts have explored the vein for a distance of 150 to 200 feet. Their new tunnel is 77 feet vertically below the first, its length being 90 feet from opening. From the lower tunnel a shaft is down 25 or 30 feet, and better ore is shown there than in the upper levels. The ore is crushed by a Tremaine mill—two stamps operated directly by steam pressure—and is supposed to be worked up at the rate of three to five tons in 24 hours. The mill turns out from \$300 to \$350 a month with cheerful regularity. An extension of the Spencer mine on the north is owned by Mrs. Hilt and sons, and one on the south by Mr. Fisher of Lane Co. Both are sinking prospect shafts, and a test run of ore from each extension was run through the mill before it began its regular work upon rock from the Spencer mine. The result was satisfactory enough to keep both parties at work at the prospecting.

WYOMING.

GOLD DISCOVERIES.—A special dispatch to the *Examiner* from Cheyenne says: Information has been received here confirming the wonderful gold discoveries at Miners' Delight, near South Pass, in Fremont county. The principal discoveries are in a mountain containing an immense deposit of conglomerate or Potsdam cement, which miners say once formed the bed of a mountain torrent. Tests have been made by the first locators which show the whole body to be rich in gold. Mill runs show uniform results varying from \$10 to \$20 per ton. There are also rich placer fields in the range which parties are preparing to work when the snow disappears. The camp is reached by a stage from Rawlins on the Union Pacific railroad, a distance of 140 miles. A new road is being opened from Point of Rocks station which reduces the distance to 70 miles. The snow is still deep in the mountains, and active operations cannot be begun for two or three weeks. It is asserted by competent authority to be the greatest gold region found since the early days of California.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JUNE 6, 1893.

498,837.—DYNAMOMETER—H. C. Behr, S. F.
499,122.—FRUITS-PRICING MACHINE—Burrell & Doidge, Wrights, Cal.
498,092.—HAND PUNCH—W. Carey, Forest Hill.
498,843.—LABEL-PRINTING MACHINE—N. P. M. Close, Tustin, Cal.
499,100.—HOSE COUPLING—P. H. Denoyer, Sprague, Wash.
498,780.—HOSE FASTENER—R. Franken, Pomona, Cal.
498,133.—FURNACE—J. L. Gironx, Jerome, A. T.
498,847.—HOSEY HORSE—A. T. Godhe, Pioche, Nev.
499,104.—STOOL—Graham & Curtis, Easton, Wash.
498,829.—MATCH-PACKING MACHINE—Geo. Grisel, S. F.
498,757.—FAUCET—R. Hagen, S. F.
498,738.—FAUCET ATTACHMENT—R. Hagen, S. F.
498,113.—THRASHER—Benj. Holt, Stockton, Cal.
499,114.—TRACTION ENGINE—Benj. Holt, Stockton, Cal.
498,957.—BITUMINOUS ROOF MACHINE—J. B. Jardine, S. F.
498,979.—ANALOMATOR—R. J. Kennedy, Redlands, Cal.
499,127.—WATER-WHEEL BUCKET—F. Von Lecht, Mirabel, Cal.
499,133.—CAR COUPLING—L. S. Manning, Alessandro, Cal.
499,135.—JOINT—C. C. Merrill, Riverside, Cal.
499,031.—DISH CLEANER—C. Palmes, Seattle, Wash.
The following brief list by telegraph, for June 6, will appear more complete on receipt of mail advice.

California—August G. Dammer, Alameda, roof framing rule; Wm. H. Cook, Riverside, tree support; Josiah A. Dewey, San Francisco, folding bedstead; Robt. F. Dockery, Highland Park, apparatus for irrigating; Juan W. Ernest, Los Angeles, duocax ball-tobacco; Maurice Friedberg, Stockton, self-timing attachment for bicycles; Andrew J. Haskell, San Francisco, re-sawing machine; Chas. G. Haub and J. F. Dasha, San Francisco, musical toy; Malcolm MacLeod, Los Angeles, agricultural implement; Isaac Polhemus, San Diego, bicycle attachment; Alexander J. Rudolph, San Francisco, card catalogue and index, book index and file, and continuous file and index (three patents).

Oregon—Bernard W. Carrington, Heppner, conductor's railway indicator; Ernest N. Walker, Lake View, spring snap.

Note.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible by mail for telegraphic order. American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SOLENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

FURNACE.—Joseph L. Gironx, Jerome, Yavapai Co., Arizona. No. 499,138. Dated June 6, 1893. The object of this invention is to provide certain improvements in the construction of smelting furnaces by which the inventor is enabled to extend the life of the furnace; to make it easy to remove and repair any portion which may have become worn out or destroyed; to remove the lower section or crucible from the remainder of the furnace for the purpose of discharging its contents and cleaning without disturbing the upper portion of the furnace. With this improved construction it is easy to obtain access to clean the furnace frequently, which keeps it in good running order for a long time. When it is desired to close down the furnace the screws which support the crucible are lowered so as to let the crucible down from the upper portion of the furnace, which then remains suspended by its rods. The crucible is then run out upon the car upon which it is transported, and the bolts which hold the two segments or sections together are removed so that the two halves may be taken apart. This leaves the metal which remains in the crucible loose and free from everything, resting upon the cast-iron plate. It is then easily removed from the plate, the two halves of the crucible are again bolted together, and the car run in again beneath the furnace. The screws are then turned up so as to raise the crucible into contact with the upper sections of the furnace, and the whole is ready for further operation. By this construction the inventor claims to be able to remove any portion of the furnace that may be burned out or need repairs without destroying the whole furnace.

SEPARATOR.—Fairfax H. Wheelan, Santa Barbara. No. 498,597. Dated May 30, 1893. The invention relates to that class of separators in which the separation is dependent upon the different sizes of the particles to be separated, enabling them to pass through apertured barriers, to be arrested thereby according to their dimensions. It consists in a traveling carrier having its surface provided with grooves, corrugations or channels at an angle to its direction of travel, said grooves or channels being adapted to receive and carry the material to be separated, and a fixed apertured barrier operating transversely in the grooves, corrugations or channels of the carrier in such a manner as to allow the particles of material of a given size and under to pass through the carrier and to arrest those of a larger size. The object of this invention is to provide a simple and effective separator of this class, which, while adapted to the separation of any material, according to the different dimensions of its particles, is especially adapted for separating barley and oats from wheat. Wheat, barley and oats differ from one another more in their length than in any other separating characteristics, the barley and oats being generally longer than the wheat. This distinguishing feature is utilized in this machine by allowing the shorter wheat to pass the apertured barrier while the longer grains of barley and oats are arrested.

CAR-COUPLING.—Frank M. Ryan, S. F., assignor of one-half to Walter T. Smith. No. 498,575. Dated May 30, 1893. This invention relates to improvements in automatic car-couplers which insure the coupling of the cars whenever they are brought together, and which enables the operator to uncouple the cars either from the side or from the top, without going between the cars or exposing himself to danger. This mechanism consists of a link connected by a rod with the parts to be moved to uncouple the cars, and this link is connected with two levers, one of which extends to the side and the other to the top of the car. The link is elastically so that either of the levers may be employed without disturbing the other. The coupling is simple in construction and easy of disengagement. The men do not have to leave the wheel to disconnect, so it is safe for the operator. The lock is entirely automatic, and the coupling is adapted to the use of link or pin. There is no spring. There is a side lever for yard work, and there is play enough on the pin to start each car separately. The inventor claims that a flying switch can be made with this coupler on an up grade.

WATER-WHEEL BUCKET.—Ferdinand Von Leicht, Mirabel, Lake county. No. 499,127. Dated June 6, 1893. This invention relates to that class of water-wheels in which the wheel or disk is mounted and rotates in a vertical plane, and has secured to its rim a series of buckets adapted to receive the impact of a stream of water under head or pressure. The objects of the invention are, first, to utilize the full power of the water, both in impact and reaction, and to discharge the water equally on all sides; and second, to connect the bucket with the rim in a simple and secure manner. The bucket has a concave hemispherical face with a central uprising cone, which cone receives the impact of the stream and spreads the water all over the surface of the face. The impact is central and the reaction is equal throughout the whole extent of the face.

MATCH-PACKING MACHINE.—George Grisel, S. F., assignor of two-thirds to Joseph D. Case and Frank Severio. No. 498,899. Dated June 6, 1893. The invention relates to the class of machines for packing articles in bundles, and it is especially intended for packing block matches and wrapping them in bundles. Block matches

are those formed from a single block of wood by splitting the block in different directions, the splints being held together at their lower ends by a thin web of wood, and said blocks are dipped into the material for making them into matches. In practice the blocks are divided into smaller blocks of one hundred splints or matches each. These small blocks are wrapped around their composition ends with paper for protection, and they are then made into bundles of any required number, say twelve, and wrapped with paper into packages. The object of this machine is to take these small match blocks after they have been each wrapped with the protecting piece of paper and lay them up in bundles of twelve more or less and then wrap these bundles with paper into packages. The machine is quite an ingenious one, and 33 claims were allowed upon it by the Patent Office.

MACHINE FOR PICKING PRUNES OR PLUMS.—James B. Burrell and Wm. J. Doige, Wrights, Santa Clara Co. No. 499,182. Dated June 6, 1893. This invention consists of a machine for picking or puncturing the skins of prunes and plums. It is a common practice in the drying of these fruits to cut their skins. This is done by dipping in lye, and the fruit thus cut dries much more rapidly and more satisfactorily. The object of this invention is to provide a suitable machine for mechanically cutting the skins of prunes and plums by pricking or puncturing them. The essential feature of the machine is an agitating table or other surface provided with pricking points. The fruit is supplied to the table or surface, which, by its movement, causes the agitation and advance of said fruit over the pricking points, thereby causing their skins to be punctured.

TRACTION ENGINE.—Benjamin Holt, Stockton, No. 499,114. Dated June 6, 1893. The invention relates to improvements in traction engines, and it consists in the attachment of a supplemental vertically adjustable frame with supplemental traction wheels journaled therein exterior to the main frame and main traction wheels for the purpose of increasing the bearing surface upon soft ground. The object of the invention is to provide supplemental wheels journaled in frames exterior to the main frame, said frames being movable vertically, with relation to the main frame, whereby the supplemental frames adjust themselves to inequalities in the ground, and when soft ground is encountered, into which the main wheels sink to a greater depth than is desirable, the upward movement of the supplemental frames is arrested so that the weight of the main frame is brought to bear upon the supplemental frame, and its wheels support a portion of the weight of the machine.

COLLAR AND NECKTIE FASTENER.—Charles P. Ware, San Rafael, No. 498,592. Dated May 30, 1893. This invention relates to that class of fasteners for collars and neckties in which a single body-plate carries a shanked head or stud for holding the collar, and a clamp for engaging the necktie. The objects of the invention are several and may be generally stated to be: First, providing for the wearing of a collar which by accident or design is much larger than the neck-band of a shirt; second, the holding of the collar well down to the yoke of the shirt; third, the holding of the collar firmly and maintaining the position of the body-plate; and, fourth, the fastening of the cravat in place in front and its retention in the back, preventing riding up.

TRAVELING THRASHER.—Benjamin Holt, Stockton, No. 499,113. Dated June 6, 1893. The invention relates to a traveling thrashing machine of that class which is usually joined with a header attachment by which the grain is cut and delivered to the thrashing machine from which it passes to the cleaning apparatus. The object of the present invention is to provide a novel mechanism whereby the main bearing wheels upon both sides of the machine take part in driving the carrying and cleaning mechanism and that portion of the moving parts which is situated behind the thrashing cylinder.

The Assay Laboratory at the World's Fair.

One of the most interesting exhibits of the Department of Mines and Mining is the Assay Laboratory in the southeast corner of the gallery. The analysis of ores, clays, coals, etc., on exhibition will constitute the chief work of the chemist in charge. It is interesting to note that the only furnace used in this official laboratory are the Hoskins Hydrocarbon Blowpipe and Furnaces. The Department having expressed a desire to use this well known apparatus, Mr. Hoskins furnished the laboratory with a full line of these goods. It will be well for those assayers who visit the fair to call at the laboratory, where they will, besides seeing many things of interest, meet a pleasant gentleman in the person of Prof. J. S. Cary, the official chemist in charge. Prof. Cary is a graduate of the Sheffield Scientific School, Yale College, and has spent three years in Germany under Fresenius at Weisbaden.

Business Increasing.

The J. H. & D. Lake Co., manufacturers of all kinds of Friction Clutch Pulleys, having outgrown their old quarters at Hornellsville, N. Y., have recently completed and removed to their handsome new offices and foundry at Massillon, O., where, with enlarged facilities, they are prepared to meet the growing demand of their business.

An interesting feature regarding the rapid growth of the Lake Co. is the fact that it came almost exclusively from advertising, for, with the exception of a limited amount of traveling, they have had no representative out on the road, except their card in the various class journals.

Market Reports.

The Markets.

SAN FRANCISCO, June 15, 1893.

THE METALS.—The feature in the metal market during the week has been the strengthening of tin. It has advanced rapidly, and was yesterday up to \$30 20. Copper and lead show little change from day to day.

NEW YORK, June 14.—Following are the closing prices for the week:

Silver in—					
	London.	N. Y.	Copper.	Lead.	Tin.
Thursday	38 1/2	83 1/2	10 80	3 80	19 40
Friday	38 1/2	82 1/2	10 80	3 75	19 05
Saturday	38 3/4	82 1/2	10 80	3 75	19 05
Monday	38 3/4	83 1/2	3 75	20 00
Tuesday	38 3/4	83 1/2	10 80	3 72 1/2	20 00
Wednesday	38 3/4	83 1/2	10 60	3 70	20 20

New York Specie Movement.

The specie movement at New York from January 1st to June 3d was as follows:

	Imports.	Exports.
Gold	\$5,928,192	\$67,667,192
Silver	1,163,350	12,126,316

Total.....\$7,091,542 \$79,793,508

For the week ending June 3d, the gold shipments were \$6,510,900, the largest in some time, and the silver shipments were \$787,503.

Public Money in San Francisco.

J. P. Jackson, Assistant Treasurer United States at San Francisco, reports cash on hand May 31, 1893, as follows:

United States notes	\$44,741 00
Treasury notes, 1890	2,685 00
National Bank notes	15,475 00
Gold certificates	440 00
Silver certificates	179,070 00
Gold coin	27,169,933 00
Standard silver dollars	24,078,794 00
Subsidiary silver coin	3,561,885 80
Minor coin	15 953 49
Total	\$55,068,977 49

Standard dollars shipped in May.....\$62,500 00
Fractional coin shipped in May.....\$65,450 00

Mining Share Market.

Business on Pine street has been quiet for the past week. There have been some irregular fluctuations, but the changes in price have been very small indeed. There are the usual rumors of improvements in some of the Comstock mines, which have kept prices changing, but there is very little interest in the news from those mines. Owing to the frequent drafts in the mines, Comstock miners are daily leaving for new camps, and lately many with their families have taken their departure from the lode, says the *Chronicle*. Every departing train carries away some miner. The mining population of Virginia is rapidly dwindling, and it is doubtful whether the major portion of those departing will ever return.

Mr. Eckart is still at work trying to get information about deep pumping, but he finds it hard work to find the figures he wants to base his calculations upon. The books were not kept with such an object in view. His report, however, will be a valuable one when completed, as he is going into the subject very thoroughly.

Practical Hydraulics.

A Book for Civil Engineers, Miners, Millmen, Hydraulicians, Mining Engineers, and Irrigators.

By P. M. RANDALL.

This new work is by one of the most experienced hydraulicians of the country. It abounds with useful tables for ready reference, in which the results of abstruse calculations are all placed in a form so that one can find what he wants in a moment. For the engineer the principles, formulae, coefficients, etc., are given; and for those not familiar with higher mathematics, examples, rules, and tables are prepared. Thus the needs of the scientist and the practical miner or millman are each met. It is the most complete work on the subject yet published, and is especially applicable to the Pacific Coast.

Table of Contents.

The following brief abstract of the contents will give an idea of the branches of the subject treated: General Plan; Discussion of the Principles of Hydraulics; Rules Deduced from Formulae Obtained; Examples and Calculations; Extensive Tables for Ready Reference and Explanation in Formulae and Rules; Flow of Water through Openings; Weir Coefficients; Triangular Weirs; Flow of Water over Quadrant Weir (tabulated); Application of Tables; Submerged Orifices; Flow through Orifices in Thin Partitions; Tables and Applications; Miners' Inches; Tables and Calculations; Flow of Water through Short Tubes and Compound Tubes; Flow of Water through Pipes; Tables of Velocities are Cubic Feet Flow for Given Fall per Mile and Diameter of Pipe; Coefficient for Bend—Circular and Angular; Flow through Nozzles; Inverted Siphons; Flow of Water in Open Channels; Extensive Tables; Rough and Ready Notes; Hints for Speedy and Approximate Estimates, etc.

Price, \$2.00, post-paid. Sold by DEWEY PUBLISHING CO., Publishers, 220 Market St., San Francisco, Cal.

The State Mining Bureau Museum.

One of the very best and largest collections of ores, minerals and rocks in the United States is that of the California State Mining Bureau in the Pioneer Building in this city. The nucleus of this collection was made by the State Geological Society, which turned over what it had when the Mining Bureau was organized in 1880. Immediate and active steps were taken to increase the collection, which met with great success, and from that time the museum has been almost daily enriched by donations from all parts of the country. While some specimens have been purchased, almost the entire collection is the result of gifts. The most frequent individual donor is Mr. J. Z. Davis, one of the trustees, who has made quite extensive purchases, which he has added to the Bureau's museum. The miners throughout the coast have contributed whatever they found rare or interesting, and much has been obtained by exchange with other institutions. Under the organic law of the Bureau this museum must be maintained in this city, and it has become now one of the places which

tourists visit. Thousands of people go to this museum annually to get an idea of the mining products of California. The arrangement of the specimens is quite complete,

photographs. The smaller specimens are all displayed in handsome glass cases while the larger ones are placed upon shelves. The ores and minerals are arranged in

groups according to their nature, and there is also a grouping by counties. The whole is very convenient for the student or any one in search of information about the varied mineral resources of the State. This collection was largely drawn upon to make up the California display at the World's Fair.

The State Mining Bureau is now in a better condition than ever before to be a practical use to the mining community. The recently-appointed State Mineralogist, Mr. J. J. Crawford, is a gentleman of education and experience well-fitted to fulfill the duties of the office. He is determined to keep the practical features fully in view and to obtain all desired information for the working miners of the State. This will be systematized so as to be readily available on application. In preparing his reports he intends to employ those having special knowledge on subjects con-

VIEWS IN THE MUSEUM OF THE STATE MINING BUREAU, SAN FRANCISCO.

and they are all scientifically classified. The views given will convey a good idea of the general appearance of the museum, though only a portion can be shown in the

connected with mining and metallurgy, and is prepared to issue bulletins or monographs relating to the several branches of the mining industry in California.

Comment.

The famous old Eberhardt mine, in White Pine, Nevada, is closed down for the manager had no longer hope of finding ore in paying quantities as the upper levels are worked out and the lower levels contain nothing of any great value. The Monitor mine, also belonging to the New Eberhardt Co., Limited, of London, shows no large returns, though it is self-supporting. They have spent £20,000 to test the property though the estimate was £10,000. This did not give the shareholders special confidence in the directors or manager, so at a meeting the other day in London, they decided to quit silver mining altogether in Nevada and turn their attention to gold mining in South Africa. They are going to buy, for £75,000, the Thistle Reef gold mine, near Barberton, in the Transvaal. The directors were ordered to complete the purchase of the gold property, which consists of 20 claims with a total length of 3100 feet. The Eberhardt and Monitor mines in Nevada are to be sold. This will end the career of this once famous company on this coast. Like other London investors they are looking for gold mines and going to South Africa after them.

The metallurgy of the precious metals and of iron and copper is much further advanced than that of lead. Percy, the great authority on metallurgy admitted, after spending some years at the subject, that the chemical changes involved in the metallurgy of lead were still unexplained. We have recently in this country a fine and exhaustive treatise on this subject by Hoffman, entitled "The Metallurgy of Lead," printed by the Scientific Publishing Co. At the last annual meeting of the Royal Society, held in London, Mr. J. B. Hannay read an exhaustive memoir on the metallurgy of lead. Having been read before this distinguished body it is entitled to serious consideration though some very startling statements were made. Mr. Hannay proceeded to describe several new volatile compounds of lead the discovery of which gave the key to the solution of many of the difficulties which had hitherto beset the path of the investigator, and by examining all the furnace reactions of lead compounds in the light of those discoveries he was enabled, he said, for the first time, to present a true explanation of the metallurgy of lead, founded upon accurate knowledge. The process consisted in passing a stream of air through the lead ore in a Bessemer converter, by which simple means the whole of the ore was converted into pig lead, or litharge, or sulphate of lead, as might be required—thus enabling the manufacturers to make the product bringing the best price in the market. The oxidation of the ore supplied all the heat required to conduct the process, so that no fuel was required. The importance of this new process, Mr. Hannay declared, might be judged from the fact that not only was the whole of the lead obtained as finished products without loss, as against a 20 per cent loss by the old method, but every ounce of silver was separated and collected without any expense, no matter how little silver might be present.

The Anti-Debris Association and the Caminetti Law.

A few days since the California State Building at the World's Fair was formally turned over as complete to Governor Markham, as the representative of the people of this State. In accepting the building from the Commission, on behalf of the people of California, Governor Markham made a speech, in the course of which he said:

"While we are all proud of the financial standing of this Nation, California must be credited with furnishing the gold that saved this country in her direst need. And, sir, let me say right here that three-fourths of that gold was taken away without leaving to California a farthing to show for it, so far as her internal welfare was concerned; in fact, but a small portion of it was left to California for the exclusive use of Californians. Yet it saved the financial credit of the Nation and placed her in the prosperous condition she occupies to-day. The Nation is welcome to it, for California can still 'keep house' without it, and she is able to continue doing these charitable acts with her usual becoming modesty. Between the years 1843 and 1878 California produced for the use of this country \$1,185,550,000 in gold, and since 1878 \$220,000,000. In addition to this she has produced many millions in silver, all of which she has contributed to the financial interest of the whole country. It is safe to say that locked up in our hills to-day, awaiting the action of the Federal Government to aid in its extraction, we have as much gold as has already been taken out; and I am convinced that this Government can resort to no means so certain, so speedy, and so economical for furnishing it with gold to restore its depleted treasury as to permit hydraulic mining, now enjoined in the Federal courts, to be carried on in such a manner as not to destroy agricultural and horticultural interests."

At about the same time the Californians in Chicago were listening to their Governor's opinion of the gold mines of the State, and his suggestion for increasing the output of gold to help the Government, the Executive Committee of the State Anti-Debris Association met at our State Capital and passed the following resolutions:

WHEREAS, The State Anti-Debris Association is organized for the purpose of protecting the rivers and valleys of the Sacramento valley from the injurious effects of hydraulic mining; and, whereas, a measure has been passed by the Congress of the United States, known as the Caminetti bill, providing that hydraulic miners may apply to a commission for permission to mine if they can do so without injury to the interests of the Sacramento valley, and providing that any hydraulic mining contrary to its provisions is a crime against the United States.

Resolved, By the State Anti-Debris Association, that, for the purpose of placing on record its position on this question, it be declared:

1. The lands and rivers of the Sacramento valley must be preserved from injury by hydraulic mining from whatever source such injuries may come.
2. That this association rests its claims on the decisions of the courts and the Constitution of the United States, declaring that the interests of the valley cannot be injured nor its property ruined.
3. That the so-called Caminetti bill is a measure proposed by the miners and has never been accepted by the State Anti-Debris Association as a solution of the difficulty. That the only question in which this valley is interested is freedom from injury, and if the Caminetti bill accomplishes this result the association asks nothing further, but if, under this bill, the injuries that have done us so much damage in the past continue, we shall stand on our constitutional rights affording us full protection to our property, and we shall resort to the courts to secure this protection, if necessary.
4. That we propose in the meantime to take advantage of all the clauses in our favor prohibiting hydraulic mining, save under the provisions of this bill.
5. That we do not believe, from our experience in the past, that dams can be erected which will protect the rivers and the lands of the valley from injury if hydraulic mining is resumed, and we reserve the right to appeal to the courts if, by the operation of the said bill, hydraulic mining should be resumed to our injury.

Governor Markham was chosen by the people as chief executive of this State and represents the 57 counties of California. The State Anti-Debris Association is a self-constituted organization representing five counties of the State.

As between the two opinions concerning the resumption of hydraulic mining, it is easy to see which will have the most weight with the public.

Moreover, these preambles, resolutions and opinions can not well change the laws which have been made for the express purpose of rehabilitating the great industry of hydraulic mining. The Congressional law is still untried, but the special commission to carry out its provisions has been organized and is ready for work. It will be time enough to declare the law a failure when it is so proven.

The declaration of the Anti-Debris Association that it does not believe in the efficacy of dams to restrain debris carries no weight whatever, since none of the Executive Committee are engineers and their opinion on such a subject is of no value. When Congress appointed Commissioners to inquire into this matter they reported that the dams would restrain the injurious part of the debris. Thereupon Congress passed laws providing that such dams or restraining works could be built. Now that the Commission is ready to issue licenses to mine behind dams the Association comes out in opposition to both the law and the dams.

It should be remembered that this new law, known as the Caminetti Act, was passed by Congress at the special request of the Legislature of the State of California. The San Francisco Chamber of Commerce, Board of Trade, San Francisco Supervisors, and those of other counties, all passed resolutions asking Congress to pass this law. Now that it has been passed it is only proper that it should be given a trial. The Anti-Debris people themselves were supposed to be satisfied with the law, but it seems it does not look so favorable to them as first appeared.

The Association, however, has now placed itself on record on these resolutions. It has placed itself in opposition not only to Congress, the Legislature, the other public

bodies referred to, and to the engineers themselves, but also to public opinion, which is entirely in favor of seeing the miners increase the output of gold, if they can do it without injuring the rivers. The miners cannot do this without the dams, under the law, and the Association condemns the dams.

The action of the Association will be looked upon generally as that of a lot of fanatics who are able to see but one side of a question, and who have been fighting the miners so long that they do not want to "let up" even when the fight has been taken out of their hands. It will do no harm whatever to the mining industry of California. The question is now in the hands of a competent commission of engineers, and it is not probable that they will permit the members of the Executive Committee of the Anti-Debris Association or any other individuals to influence their opinion one way or another in the slightest degree.

Mill-Work, Concentrates and Tailings at Bodie.

There are some very interesting statements in the last annual report of the Standard Consolidated mine of Bodie. Manager Thos. H. Leggett is a very accurate man and details of operations are carefully presented in the report. The 20-stamp mill has run steadily the past year and has crushed 632 tons more than in the year previous at a cost of 36½ cents less, per ton milled, and with 41 per cent higher extraction of value. The total crushing was 16,336 tons, of an average value of \$19.92, of which \$17.93 was gold, the balance silver. They saved 72.45 per cent. The cost of milling per ton of ore for the year including all treatment of concentrates, vanner tailings, etc., was \$3.52½. The percentage of free gold obtained from the apron plates was 85½ and from the battery sands 14½ per cent. The consumption of quicksilver on the plates per ton of ore crushed was four-tenths of an ounce. They treated 123½ tons of concentrates in the year, the percentage of which in the original ore was two-thirds of one per cent. These were worth \$89.83 per ton of which \$58.97 was gold. Each stamp crushed per day 2.42 tons. The stamps drop 6 to 7 inches and 104 times a minute. They weigh 750 pounds each. The screens are 40-mesh punched tin. In this mill no quicksilver is fed into the batteries but its sands are amalgamated in pans at each month's clean-up.

The table giving a summary of the mill work for the year shows a total ore value of \$325,735.30, which is less by \$18,553.18 than the previous year. The bullion product, however, was but \$138.30 less than in that year, and the total milling cost, including cost of treating concentrates, vanner tailings, and all work done in the mill, was but \$57,884, against \$61,002 for the previous year. It is expected that this cost will be much further reduced during the coming year by the use of the electric power plant, the description of which, from the same report, was printed in the last number of the MINING AND SCIENTIFIC PRESS.

They treated by pan amalgamation 123½ tons of concentrates from the Frue concentrators with an average extraction of 81.6 per cent, or nearly 2 per cent better than formerly. The tests made the previous year were convincing as to the economy of this method of treatment, and it was then stated that a further yield would be obtained from the tailings of these concentrates (worth about \$20 per ton) after their exposure to oxidizing influences.

Last summer these tailings were plowed over several times and then amalgamated, 134 tons being put through the pans before winter weather froze up the tailings bed and covered it with ten feet of snow. A very base bullion was purposely made, barely 100 fine in gold and silver, but the extraction was very good for such material, averaging 67 per cent, and raising the total extraction on the original concentrates to 93 per cent, which is certainly as good as can reasonably be expected from any method of treatment.

The tailings from the concentrators after passing through two pointed settling boxes to get rid of the excess of water, are amalgamated by the Boss continuous pan system. They treated in this manner 11,370 tons, which yielded \$14,662.97, of which \$13,079.01 was gold. The cost of run was \$7,304.46 and profit \$7,358.51. They extracted per ton \$1.29 at a cost of 65 cents and profit 64 cents per ton. The percentage of extraction was 24.2. It was found that where the percentage of silver was high the percentage of extraction was higher, the silver evidently aiding the amalgamation of the gold.

Salt and bluestone have proved efficacious in aiding amalgamation in the pans, while the use of acid, advocated by Mr. M. P. Boss, was discontinued, as it was more expensive and gave no better results. While the work of this continuous pan system can hardly be considered good, the method is maintained in default of a better, and because it is cheap and shows a tolerable profit.

As stated in the last report, the Gold and Silver Extraction Mining and Milling Company in Denver, to whom

was sent a ton sample of these tailings, obtained an extraction of 46 per cent after twelve hours agitation of the pulp in a one-half of one per cent solution of cyanide. The Noble Mining and Milling Company also tested a 200-pound sample of vanner tailings last spring, and have since reported an extraction of but 38 per cent, adding that they "had never handled an ore from which they obtained so small a percentage of its assay value." Neither of these processes show a sufficiently higher extraction over that yielded by the present method to cover the royalty and the extra cost of either process, while they offer corroborative testimony as to the difficulty of obtaining high or even fair results from these clayey tailings. The method in use has at least the advantage of a known and positive monthly profit.

The Late Senator Stanford.

The accompanying portrait is one of the best ever made of the late Senator Leland Stanford, whose death occurred on Tuesday. He was a man of striking personal appearance. Daguerreotypes taken at the age of 20 show that even then he had a certain dignified bearing, belonging rather to a man of more mature years. A man of large physique in his prime, he grew more portly with advancing age, until during the past year or two he has had to confine himself to a rigid diet to keep down the ever-increasing flesh. His only exercise was riding, of which he was always fond, but for a long time he has not used fast horses or light "rigs," confining himself to a wide and very low open carriage, drawn by a pair of heavy, slow-moving horses.

Mr. Stanford was essentially a domestic man, and his wife was his constant companion. On the death of their only son they devoted themselves to the Leland Stanford Jr. University, founded and endowed as a monument to their boy. This endowment is one of the great public gifts of modern days, amounting to about \$20,000,000.

Always a lover of fine horses, Senator Stanford established the Palo Alto stock farm, and devoted himself to developing certain original ideas concerning the trotting horse, in which he was eminently successful. Horses bred by him brought wonderful prices, and were known all over the world. He bred both trotting and running horses on his farm, the two departments, however, being kept entirely separate and under different management.

It has long been his habit, while living at his country residence at Palo Alto, to go daily in his carriage to the speed track and there witness the trials of his horses. Under the shade of a big oak called the "Governor's Tree," he would sit for hours criticizing the action of his horses, consulting with the drivers and issuing orders and directions. This was his great amusement and was followed to the day of his death. He would then drive through the university grounds, past the great buildings, back to his beautiful home, where he was always accessible to those who called. On this ride he daily passed a remarkable *memento mori* in the form of the magnificent tomb erected after his son's death, and over the door of which is carved his own name, that of his wife, and his son. The bulk of the great fortune amassed by this energetic and able man in the course of his active life will be devoted to the completion and maintenance of the university. This will be now under the management of Mrs. Stanford, and upon her death, devolves upon a hoard of trustees, already chosen and clothed with suitable powers.

No other Californian has ever occupied such a position before the public as has Leland Stanford. Coming here as an humble prospector and miner, then engaging in business as a merchant, he developed into Governor of the State, United States Senator, one of the great railroad builders of the age, president of a great system of railways, and, finally, the founder of a noble university devoted to the free education of the children of the land. In his death California loses her foremost citizen. No other name is so closely related to her material or political history.

LEAD seems to be following silver on its downward course.

PREPARING REPORTS FOR THE DERRIS COMMISSION. Messrs. Striedinger and von Geldern, civil and mining engineers, have become associated to make surveys and examinations and to prepare the required technical drawings, estimates and reports called for by the California Debris Commission in a circular issued June 8th, and published in the MINING AND SCIENTIFIC PRESS. These gentlemen are prepared to represent the petitioner in laying the case properly before the Commissioners. Mr. von Geldern has had considerable experience in river work in California and assisted the Briggs Commission in obtaining data about sites for dams, etc., and Mr. Striedinger is a mining engineer of experience. As the Commissioners prefer to have each case by a mining or civil engineer, these gentlemen have formed a partnership to represent such miners as may require their services in preparing the necessary papers and placing the case before the Commission.

THE FRIENDS OF THE MINING AND SCIENTIFIC PRESS are reminded that the close of the volume occurs with this

THE LATE LELAND STANFORD.

number, and that this is a good time to suggest to others that they should become subscribers. The index on the last page shows what a variety of topics have been treated. They cover most branches of mining, metallurgy, mechanics and practical science. Those interested in any of these matters can readily afford to place their names on the subscription list of the only weekly paper on this coast devoted to these specialties. Those who are already readers can greatly aid the paper by calling the attention of their friends to its merits and its usefulness. The mining community in particular should aid in every way in supporting a journal which devotes so much attention to the mining industry.

DIRECTIONS have not been given for the immediate resumption of work on the Bunker Hill and Sullivan mines in the Cœur d'Alene district, Idaho, as has been stated in some of the papers. The company has not yet settled its differences with the railroads.

Prospecting Drift Mines by Boring.

Mention was recently made in the MINING AND SCIENTIFIC PRESS that at the May Flower drift mine, on the Forest Hill Divide, Placer county, they were prospecting a cross-channel to find its center by means of a boring outfit. Since then we have learned some of the particulars from Mr. Felix Chappelet, manager of the mine. The boring is done by means of an ordinary artesian well outfit, the tools for which were made in this city. In addition to the derrick there are auger stems, sinker bars, bits, reamers, sand pumps, etc. The holes bored are six inches in diameter. One of them is 176 feet deep, passing through 26 feet of auriferous gravel, and a new one started is expected to go down 415 feet. This fourth hole is now down 120 feet and is progressing at a rate of over 10 feet per day. In one of the holes they made 25 feet a day for the first two days and sometimes go from 15 to 18 feet a day. The upper lava through which they are working is, however, rather hard.

This work is being done to find the center of a side channel. The 415-foot hole now being bored is intended for ventilation purposes in the Orono channel of the May Flower mine. The pipe will be left in, and at the bottom an elbow will be put in and the pipe led off 1000 feet to get an up-draught. It is an experiment, but they have great hopes of success. In this work double shifts of two men each are worked day and night, and it is not found to be at all expensive.

The May Flower mine is now quite profitable and is paying dividends. The last returns were \$17,583 from 14 days' run, representing gravel worth \$15.80 per ton—one of their carloads representing a ton. The tunnel is in 13,500 feet. There is then a raise of 45 feet from the tunnel to the gravel. The channel is worked from five to seven feet in height and 100 feet in width. The cars are run by horses, and there are two stations.

The May Flower is one of the principal drift mines in this State, and one in which there are very extensive developments. While the tunnel was being run, the assessments and expenses were very heavy, but that period has long passed, and they are now reaping their reward on the investment and labor.

The Eureka Consolidated is another drift mine, 13 miles above the May Flower, on the same Divide. It has a tunnel in 1645 feet and 210 feet in the channel running from the east stream to the west stream. This is under the same management as the May Flower, Mr. Chappelet being superintendent. The Board of Directors, organized a few weeks since, consists of Col. Herman Bendel, Felix Chappelet, Rudolf Herold, Daniel Hayes and D. M. Kent. Some of the shares are to be sold for working capital. This gravel can be washed, and no mill will be needed to prepare it.

Boring in the way described to find the channel center greatly simplifies the drift mining problems, for the miner can then tell exactly how and where to run, and there is no danger of getting a tunnel or drift too high for the best gravel, as has often happened. So far the experience has been favorable, the cost of

the holes being low and the work being carried on quickly.

THE owners of lead-producing mines are wearing long faces on account of the low price of lead. They say that lead cannot be mined at less than \$3.50, and if the quotations drop five cents lower they will be compelled to close down their works. The smelters also feel the depression, and they stand in the same position as the miners.

THE gold mining sections of California are overrun with men seeking work who have flocked there from silver districts in other States. As there were plenty of miners to carry on the work already there the new arrivals are generally compelled to remain idle or seek some other line of labor.

It is reported that all work has been suspended at Eberhardt, White Pine county, Nev., and the miners and their families have left that place for Taylor.

Coast Industrial Notes.

A CAR load of machinery has been shipped to La Porte, Plumas county, consisting of a complete outfit for a first-class saw mill for the Slate Creek Gravel Mining Company of that locality.

THE engine in the Navarro Company's lumber mill, at Navarro, Mendocino county, ran away the other day and the fly-wheel went to pieces, wounding three men, one of whom will die.

THE PLACER *Argus* says: L. I. Ogden went to Iowa Hill Saturday night last to put in running order at the Morning Star mine an electric dynamo to be used in lighting the works, tunnels, etc., of that property.

THE Denver Iron Works are now building a copper matte furnace for the reduction works at Reno, which will soon be shipped and put in place, and all ores containing gold, silver, copper or lead will be sampled and paid for at the works.

HENRY RYAN, a resident of San Diego, has been appointed Chief Engineer for the Los Angeles, Owens Valley and Utah Railway, and in a few days will begin the survey. The company's plan is to build the gap of 153 miles between Mojave and Independence.

THE mining outlook in White Pine county, Nev., is brighter than for a number of years. Twenty men were put to work in the Chinaman mine at Ely a few days ago, and the company which has taken hold of it will spend considerable money in developing the property.

THE engineers of the Southern Pacific Company are working on plans for a new steel bridge across the estuary at the foot of Harrison street, Oakland. It is proposed to remove the two old bridges that now span the estuary at Webster and Harrison streets. The new bridge will be a very large one and will do all the work of the two bridges. The present bridges do not meet with the requirements. The draws are too small, and a big vessel dare not take the chances necessary to get into the Brooklyn basin. They are only 80 feet wide in the draw and should be 120 to meet legal requirements.

A DESPATCH from San Diego says: A big transfer lighter, owned by the Development Company at San Quentin, has been bought by the New Padara Onyx Company and will be repaired and then taken to San Carlos landing. A force of men under Bell & Son will go down on the Pacheco with a supply of lumber. The Pacheco will tow the big lighter down on her next trip. The lighter is 140 feet long and 32 feet wide, and will be moored at San Carlos landing by heavy mushroom anchors, and Superintendent Foote of the onyx company expects that by the new arrangement the loading of onyx can proceed in any reasonable weather. Shipments of the stone will be at once largely increased.

IN accordance with instructions from the Bureau of Yards and Docks at Washington, D. C., there will be an extra large force of laborers taken in the Yards and Docks Department at Mare Island Navy Yard as soon as possible. This movement is entirely unexpected, and has more than ordinary significance attached to it from the fact that its advent is due to the recommendations of the Board of Officers who recently inspected the navy yard with Captain E. O. Matthew as president. It has been ascertained that the men to be taken on in consequence of the order mentioned will be employed in cleaning the navy yard of innumerable heaps of debris and other refuse scattered about the yard at various points and adjacent to the various shops.

CAPTAIN CHARLES MINOR GOODALL, Captain Edward Goodall and John L. Howard have returned from their inspection trip to the Ocoa bay mines in Southwest Oregon, which were lately purchased by Goodall, Perkins & Co. from the Oregon Coal and Navigation Company. The mines were found in excellent condition, but only enough coal is being taken out at the present time to supply a full cargo for the steamer Arcata. This was the first general inspection since the mines passed into the hands of the new owners. "When the steamer Arago, now having fine passenger accommodations built on her at the Union Iron Works," said Captain Goodall, "is ready to go on the route, which will be in about three weeks, we may make a change. She carries more cargo than the Arcata and the output of the mines will have to be increased sufficiently to give her a full cargo."

ANOTHER important enterprise in the way of water development is about to be inaugurated in Otay Valley, San Diego county, where Joseph A. Flint, in manner prescribed by law, laid claim to water flowing in Otay creek. About two years ago Flint constructed a dam across the channel above the named point and twenty feet below the water level at bedrock, and he now proposes to clear off the bedrock immediately below the old dam and strengthen the latter by adding forty feet more cement until the height of the present structure is reached. From then on work will proceed until fully 100 feet high, forming a reservoir of 65,000,000 gallons capacity, and affording a continuous flow of 5000 inches of water. The water thus obtained is to be used for irrigation, mechanical and domestic purposes in Otay, Ocoenta, Chula Vista, National City, San Diego, Coronado Heights and South San Diego, and will be diverted by means of a conduit eight feet wide by four feet deep, or pipe or ditch of equal capacity. A force of men has been put at work grading the road to connect with the main highway, and hauling the material necessary to construct the dam.

A DRAFT INDICATOR has been invented which is intended to be placed at either or both ends of a vessel for the purpose of showing at a glance to the officer of the deck how much water his vessel is drawing. It may also be set at any desired point, so that when a certain draft is reached a signal bell is automatically sounded, and continues to ring until stopped. This is effected through electric connections. The accurate working of the instrument can never, to the slightest extent, be affected by the rise or fall of waves.

Mining Notes from Siskiyou.

TO THE EDITOR:—Several San Francisco mining men have arrived in Yreka within the last week, who are on their way to visit mines in this and adjacent districts, and quite a number of prospectors from other sections of the country have passed through here on their way to the Salmon River country and other districts near by. Mr. C. W. Ayers, Mining Commissioner for the State of Oregon, passed through this place en route to his hydraulic mines on Shackleford creek, west of Quartz valley. Mr. Ayers states that this has been a very favorable season for placer mining in that section, and that in all probability the yield of gold from that district this season will be good. The Fort Jones Company are opening up their claim, which is situated a few miles north of Mr. Ayers' mines, on the same channel which runs through the range laying west of Quartz valley. Mr. H. C. Chester is developing his new property, which he purchased a short time ago on the east side of the valley. The ledge prospects well and Mr. Chester states that it promises to become a good paying mine.

The trail across the mountains from Etna to Sawyer's Bar has been open now some three weeks, but the road will not be passable for wagons for nearly a month yet on account of the heavy snowfall of last winter, which still covers the mountains to a considerable depth. The latest reports from Sawyer's Bar and vicinity are flattering, to say the least. A man who came over from there to-day stated that George Shaw, John Finlay and James Johnston struck a pocket on Jackass creek, five miles from Sawyer's Bar, three days ago, and that they have already taken out over \$1000, and that the pay still continues as far as they have worked.

It is also reported that a very rich pay chute has been struck in the Daggett mine, and that it is the largest and richest body of ore that has been struck in that camp for years. Alex. Parker & Sons have some good property over there that bids fair to make a good showing this season. The road across Scott mountain to Trinity Center is now open, several teams having crossed lately. Prospectors are coming in every day to the towns in Scott valley on their way to the mountain districts.

The mining districts embraced in Siskiyou county, which in the past, like southern Oregon, have been thought but little of by the outside mining world, are now attracting the attention they justly deserve of both capitalists and prospectors. The old prejudice against this section is rapidly passing away and confidence in its future mineral productiveness is fast taking its place. There is a large area of mineral country in this county that has been prospected but very little in the past, which, beyond a doubt, will become good paying districts at no distant date, and there are many opportunities for as profitable an investment of capital in this county as can be found anywhere on the coast to-day. Of course those localities have their drawbacks, like all other districts which are undeveloped, and seasons are not one perpetual summer's day, and you cannot drive a four-in-hand over a level macadamized road to all the mines, as some of the "natural-gas" capitalists and "whisky-bar" prospectors expect, and when they do not find them denounce the country and locality and pronounce it "no good," which expressions they themselves are the truest and simplest definition of. What Siskiyou county wants to develop its mineral resources is prospectors with brains and willing hands, who are not afraid of a little physical exertion, and capitalists with good sound judgment who are not afraid to back it with their money to prove their judgment correct, to their own profit and the benefit of those whom they employ. When that class of men become interested here the mutable and detrimental class, whose sole object seems to be to profit at the expense of others without any exertion or risk on their own part, will no longer be an injury to Siskiyou county's progress. Fort Jones, June 15, 1893. ALEX. QUARTZ.

Electric Locomotives in Mines.

"At the No. IV pit of the Mines de Marles, near Bethune, Pas de Calais, France, traction by electric locomotives has been applied experimentally in two galleries, driven in opposite directions, the northern one being new, and representing more favorable conditions in regard to inclination and humidity than the southern, which is considerably older. These have been chosen in order to arrive at the conditions under which the system can be most advantageously applied. The installation supplied by the Edison Co. is designed to work two locomotives capable of developing ten horse power with a current of 30 amperes and 400 volts, and utilizing 70 per cent of that given out by the dynamo. The engine, with cylinder of 400 millimeters (15½ in.) diameter, and 800 millimeters stroke, making 65 revolutions per minute, drives the dynamo by means of a belt at 840 revolutions. The main conductors on the shaft are insulated cables of copper, nine millimeters (0.35 in.) diameter, supported on porcelain knobs at intervals of 30 meters, which are connected with a switchboard at the pit bottom for turning the current either to the north or south gallery, as required. The conductors in the gallery are flange rails weighing 6½ kilograms per meter (13 lbs. per yard), which are hung from the roof and insulated by discs of india-rubber.

"The locomotive is a 15 000-watt series dynamo, mounted on an iron carriage with two axles, which are driven by an intermediate shaft and toothed gearing, the axis of the dynamo being parallel to the road. The current is taken from the conductors by two small carriages drawn by the locomotive. The electromotive force, and consequently the power of the engine, may be varied by a rheostat placed on the circuit, which acts upon the magnetic field of the main dynamo, so that it is very easily controlled. There is also a quick-acting disconnecting gear at either end for admitting or cutting off the current for the locomotive, as well as a reversing gear for changing its direction. The dimensions are: Length, 2.30 meters (7.54 ft.); breadth, 0.72 meter, and height, 1.50 meters. The weight, which was originally 1800 kilograms, being insufficient for the south gal-

lery, where the adhesion is deficient, it has been increased by the substitution of solid wheels and counterpoises to 2300 kilograms, which is found to give perfect adhesion and stability. The loss of current on the line is imperceptible.

"By useful industrial effect is meant the work moving the train apart from the engine. The effect of the moderator is only to limit the quantity of current, but not to regulate it. When closed, as on the first and fifth experiments, the current varies from 16 to 20 amperes; and when full open the quantity is the same, the difference of work being due to the voltage. In the fourth and sixth, with three-quarter open, there is a reduction from 30 to 25 amperes. This is due to the self-regulating character of the locomotive, which varies the expenditure of power with the work to be done. It is therefore a point of importance to keep the gradient of the line as uniform as possible, in order that the current may never exceed the maximum that can be safely borne by the rheostat. A comparison of the second, third, fourth and sixth experiments shows that it is better to increase the speed rather than the load. Electric machines work best at high speeds. In the third and fourth experiments the speed is seen to be increased 40 per cent with the same load, while the extra power expended is only 5 per cent, the maximum useful effect being obtained at a speed of 3.46 meters. This, however, is likely to be too high, except on straight roads of greater length, free from crossings and the conditions of the second experiment. The engine drawing 15 tubs at 2.50 meters, (9 kilometers per hour) speed will probably be more suitable. At this rate the engine could furnish in coal drawn 243 ton-kilometers in the shift of eight hours. With horse-traction, having regard to the bad state of the road, five horses (four at work and one relief) will be required to do the same amount of work. The two locomotives, therefore, when in full work, the only conditions under which they can be profitably employed, will replace ten horses."

Employees as Stockholders.

President Fish of the Illinois Central Railroad Company has issued, at Chicago, the following circular to the officers and employees of his road. It puts in practical shape a plan that has been for years talked about and has received considerable publicity:

An expression on the part of many of the company's officers and employees of a desire to invest their savings in the stock of the Illinois Central Railroad Company having reached the Board of Directors, they have thought that considerable saving in every department of the service could be effected by such a community of interest, and have authorized me to make to each of you the following offer, viz:

While the company has no stock for sale, it will assist any of its officers or employees to buy one share at a time at the fair market price, to be fixed when application is made, purchaser to pay for his shares in sums of \$5 or multiples thereof. Payments may be made to the treasurer, the local treasurer in New Orleans, the paymaster or the assistant paymaster. On the amounts so paid interest will be credited at the rate of 4 per cent per annum, and when the sum at the credit of any purchaser amounts to the price at which the stock was bought, he shall receive a certificate for his share of stock, and can then, if he wishes, begin the purchase of another share. The certificate of stock is transferable on the company's books, and entitles the owner to such dividends as may be declared by the Board of Directors, and to a vote in their election.

Any officer or employee making payments on this plan can have his money returned to him, with interest, on application, through the proper channels, to the head of the department in which he is employed.

Should the purchaser make no further payments during 12 consecutive months interest shall then cease to accrue on his payments, and the sum at his credit will be returned to him with the accrued interest on application.

In case a purchaser leaves the service of the company from any cause he must then either pay in full for his share and receive a certificate therefore or take his money with the interest accrued to the date of his leaving the service.

The foregoing does not preclude the purchase of a large number of shares of stock for cash.

Any employee desiring to so purchase should apply to either of the representatives of the treasury department named above, or to his immediate superior officer.

I sincerely trust that this offer will be accepted in the spirit in which it is made, and will be generally availed of for our mutual benefit.

THE company that erected the smelting works at Ketchum spent over \$1,000,000 in plant, mines, ores, supplies, etc., and failed to make the institution pay. A smelter was operated at Hailey in 1881-82, but it finally collapsed after its owners had sunk many thousands of dollars in the vain endeavor to make it pay. Another at Bellevue met with a like fate.—Hailey Times.

A. S. HALLIDIE, president of the Mechanics' Institute, went to Chicago last week, and will there arrange for the exhibit, in this city, next winter, of such articles now in the fair as the owners may desire to have the Pacific coast see. The exhibits will form a portion of a Mechanics' Institute Fair and will be shown in the pavilion or elsewhere, under the institute's auspices.

FIRESIDE MINING.—Since the closing down of the Standard mine the men have done a wonderful amount of prospecting. Tunnels have been driven, shafts sunk, lost ledges found, and old and abandoned mines thoroughly explored and opened up. Nearly all these gigantic enterprises, however, have been carried out around a hot stove in McAlpin's saloon.—Bodie Miner.

THE third annual Southwest Silver Convention and Mass Meeting of Miners will convene in Silver City on the 4th and 5th of July, 1893, at 9 A. M.

Progress in Metallurgical Industries.

Steel in the rough, says the New York *Sun*, is now sold at Pittsburgh at \$21.75 per ton of 2240 pounds—a fraction less than a cent a pound. In 1867 steel rails at the same mart were \$166 per ton; in 1872, \$112; in 1882, \$48.50; and to-day \$30. How has a result so surprising been brought about? Why is it that the United States last year manufactured 4,277,000 tons of steel against 3,679,000 tons produced by Great Britain, with promise that the interval between these two great rivals will widen rather than diminish as the years roll by?

First and chiefly, from the richness and vastness of the iron mines of this country, and the good fortune that many of them—especially in Pennsylvania, Alabama and Tennessee enjoy—enjoy in being contiguous to coal beds; and where, as at the mines of the Vermilion range, in northern Michigan, fuel is remote, water transportation charges to the furnace regions are nominal.

The cheapening of steel is in the main to be credited to the so-called Bessemer process, first devised by William Kelly, who, in 1847, at the Eddyville Iron Works in Kentucky, refined molten iron by a blast of air in an acid-lined vessel. The English inventor developed this principle of burning the superfluous carbon out of iron until only steel remained, with so much ingenuity and boldness that his name is indissolubly linked with the process. While that process is employed in manufacturing much the larger part of our American steel, the open-hearth furnaces devised by Siemens and Martin are steadily gaining in favor. The first of them to be built in the United States was erected at Trenton, in 1868, for Cooper, Hewitt & Co. Phosphorus in steel makes the metal brittle, and as many ores of iron, particularly those of the southern States, contain a notable percentage of phosphorus, it was an important discovery when in 1879 Mr. Sidney Gilchrist Thomas perfected his so-called basic process, by which such ores can be made into excellent steel. In England the bane becomes a blessing, the slag from a basic furnace, containing as it does much phosphoric acid, yielding a valuable fertilizer. Mr. Thomas' discovery was first applied in America to an open-hearth furnace in 1888, at the Homestead Steel Works of Carnegie, Phipps & Co. There are now six open-hearth steel works in this country. In the adaptation of a particular process to a special ore, carrying sulphur, phosphorus, or what not, a considerable economy is realized.

Of still more influence in the cheapening of steel is the introduction of machinery in mining both ore and coal, in getting out the limestone to be mixed with the coal and ore, and in saving manual labor at every stage of the manufacturing process. At the Carnegie Works in Pittsburgh is the most elaborate and costly mechanical plant in the world, one machine alone representing an outlay of a million dollars. Remarkable also is the steady gain in the efficiency of ore, coal and limestone, as furnaces have been increased in size and improved in design. The *Engineering and Mining Journal* recently gave some details taken from the accounts of a well-managed, typical concern. In 30 years ending with 1892 the coal required to produce a ton of pig iron had been reduced 37 per cent, the ore 20 per cent and the limestone 50 per cent. The saving in the manufacture of steel, of course, parallels these figures.

After the British and German mining engineers had met their American brethren in New York in October, 1890, they visited the leading iron and steel works in this country. What chiefly struck them was the pace at which operations were forced to a finish. Their observation on this point receives noteworthy proof in the mining department of the World's Fair. Among its exhibits are contours of the largest furnace in Great Britain, that at Newport, and the largest in the United States, that of the Edgar Thomson Works at Pittsburgh. The English furnace has a capacity of 30,000 cubic feet, produces daily 70 tons, uses 2308 pounds of coke to a ton of product, with 150 hours as the time of a furnace operation. The American furnace with smaller capacity, 18,800 cubic feet, turns out 271 tons a day, uses but 1863 pounds of coke per ton of product, and crowds an operation into 21 hours.

Beyond the causes metallurgical and mechanical which have cheapened steel are the irresistible forces of business. Competition has become exceedingly keen, and manufacturers these days have to be content with slim profits, and often with no profits at all. The bonanza years when steel works paid cent per cent are memories of the unreturning past. To-day such works must be advantaged by ample capital, and by executive ability of the first order, or go to the wall. As yet Great Britain, with its lower scale of wages, can make steel cheaper than the United States, but to this there is a significant exception in the forms of it manufactured for the architect and the engineer. The demand for structural steel on this continent is so vast as to bring down the cost of production below the British figures.

Because it is stronger and tougher than iron, steel long ago ousted iron from use as the material for rails. A steel rail lasts about ten times as long as an iron one. This, of course, has cheapened rail transportation, and so helped to cheapen steel itself by lowering freight tolls charged for hauling the ores and fuel needed to make it. As a material for machinery, steel not only wears better than iron, but can be run at higher speed. What this means in money saved in all the departments of the metal's application would require figures of astronomical audacity to express. And the end is not yet. Nickel alloyed with steel exhausts its tensile strength remarkably, as recent tests of armor steel abundantly prove. Let experiment in the preparation of this alloy come to success, as it undoubtedly will, and we shall see nickel steel enabling the architect and the engineer to take almost as long a stride ahead as when they discarded iron for ordinary steel. The time is at hand when bridge spans can be longer, towers higher, boilers, cars and engines lighter, and when machinery, driven quicker than ever, will last longer than it does to-day.

TELEPHONIC JOURNALISM is a feature of life in Budapest, and it is believed by the promoters of this novel

scheme that it will prove popular with the people. It is proposed to establish a system covering the entire city, dividing it into eight districts, all of which are to be connected to the central office. At the telephone exchange a regular newspaper bureau is conducted, the news of the city being collected by a regular staff of reporters and foreign reports being received through the regular telegraphic service. All of this is condensed into the briefest possible statement for publication in the *Telephonic Gazette*. At 9 A. M. each day the "editor" assumes his post at the central station, and begins to tell the story of the day's news. After the first budget is sent out it is repeated in order that those who may have missed anything can be fully informed. At 10 o'clock the "second edition" is ready and at regular intervals throughout the day these oral editions of the *Telephonic Gazette* are issued. In the evening lectures are reported, local entertainments are described for the benefit of the ladies, the latest attraction at the theaters are reviewed by the dramatic critic, and the young ladies are permitted to listen to a concert; "they can distinguish wonderfully well the touching pathos of the violoncello, the pearly staccatos of the violin, the sweet melodies of the flute, and the enchanting voice of the prima donna." The *Oriental Review* is authority for the statement that "by the aid of a single wire of the State telegraph line, our central station has been connected simultaneously with the telephone stations of Vienna, Graz, Brunn, and Trieste; and in all those cities the voice of the *Gazette's* editor has been heard—clear, sonorous, and with every shade of intonation." Western Electrician.

New Patent Center Line for Sinking Deep Shafts.

In anticipation of a paper which will shortly be read before some of the mining institutes of England, on "A Combined Center Line Apparatus for Sinking Deep Mines," which has been patented by W. Foulstone, of Barnsley, we are able to give in advance the following outline of the invention:

The apparatus is made of wrought and cast iron, the working parts being planed, turned and bored. The drum is made of the same material, and will take on 800 yards of center line, which can be put on as quickly at a depth of 700 yards as it can at 50 yards. The *modus operandi*, too, is so simple that an ordinary banksman can understand it in the course of a few minutes, whilst in the operation itself there is a saving in time of 80 per cent in putting on and taking off as compared with the present system. It can be adapted as a permanent fixture, being more reliable and safer than loose tackle as now used, and which has to be fixed daily or nightly by the banksman over the shaft top when the sinkers are working below. At times the wood bar with the pulley in it has been known to fall into the shaft or for the center line to run over, so endangering the lives of the sinkers when at work. The new center line, however, can easily be lowered from its position at the top to the bottom, and then pushed forward from one side to the center whilst the men are engaged in filling the hoppers or trunks, so saving all the time now used in fixing the loose bar with pulleys at the top and then having to lower the center line from the surface which under those circumstances frequently spins round for some time after the heavy weight is put on to straighten and steady it before it can be used. Then after being used it has to be drawn to the surface and the bar with the pulley or pulleys removed. The new center line, however, can be always hanging in the shaft with the weight on it and some 30 yards from the bottom, so that spinning is entirely done away with. When the winding rope is fixed to run in the middle of the shaft, the center line is lowered to the bottom and then pushed forward to the center, directly the hopper, or trunk, is raised to the surface to empty the debris. Whilst this latter operation is being carried out a man pushes the line to the center putting it in the desired position in the space of a few seconds, care being taken in fixing the apparatus in the line with the winding engine drawn and in the center of the shaft, a great advantage being gained in the setting out of the arches or porches in true line with that of the surface and with one common and unquestionable center. To do this, having first got the true center of the pit, this has to be followed up by drawing the line back to the side of it, so that by having the line accurately across the two points, the center line of arches or porches is obtained in a very few minutes. By the same means the sump frames can also be set out. It may also be said that where water accumulates quickly at the bottom of a sinking, there is often considerable difficulty in getting clear of it, and the placing of the center line is sometimes neglected, owing to the time occupied in getting rid of the accumulated water. It also happens at times that the shaft is sunk much too large in diameter, so as to be sure that it is sufficiently large without putting the line on, which requires the unnecessary space so opened out to be filled up with either debris, or brickwork, more particularly when the pit is walled-up from the surface, and so causing much additional work and unnecessary expense.—Colliery Engineer.

A MONSTER BLOCK OF ORE.—The directors of the Volcano Company, at a meeting held recently, decided to send out to the mines a force of 18 to 20 men to assist the present force in hocking out as large a piece of gold as the largest wagon will hold up. The block will be about 15 feet long and 6 feet square, weighing about 60,000 pounds. The vein from which this will be taken is 45 feet wide, with an unknown depth, and crops out on the surface for over a mile, hence a block 45 feet square by 1 mile in length could be had if there was any way of transporting it to the railroad. This one vein assays \$199 60 gold, \$81.40 silver and \$23 copper per ton. The company owns five other similar veins adjoining it and a veritable gold hill one mile north of it. The value of this ore block will be \$37,230. It will be a glittering beauty, showing silver and copper glance and native gold, intermixed with a blend of brown and green and red oxide. This large block of ore will be hauled to Sentinel on wagons, a town on the South-

ern Pacific Railway, 35 miles south from the mines, and shipped to the managers of the Arizona mineral exhibit at the World's Columbian Exposition at Chicago.—Phoenix (A. T.) Herald.

Trade Advertising Mediums.

When a daily paper has reached a circulation of 200,000, it has achieved a rare and remarkable triumph, for few indeed ever reach half that number. Yet the circulation of most trade papers exceeds that of any daily; not in the number of copies printed, but in the number of persons reached whom it is intended to reach. To illustrate our meaning, we may point out that the daily is read for its political and general information by those in every walk of life—by the farmer, mechanic, merchant, professional man and loafer. The trade paper is read only by merchants, for it contains little of interest to the general public. The ratio of merchants in every line of business, including small shops, etc., to the general population is about one to seventy. Making a division of merchants and separating those who deal in special lines from the general storekeepers, it is found that the ratio of the latter to the population is one to every ninety-five. We may select at random three counties in Great Britain with a total population of 66,000. The number of merchants in these three counties is 860, or one to every seventy-seven of the population. The number of general shop-keepers is 720, or one to every ninety-three of the population. Figuring on the circulation of a daily of 66,000, it will be seen that it reaches in that number 720 general store-keepers. Thus, a trade paper of 3000 or 4000 circulation reaches from four to five times as many retailers as a daily with a circulation of 66,000; and for a daily to reach the same number of store-keepers as a trade paper of 4000 circulation, it would require an issue of 300,000. And what daily fills the requirements? This fact is recognized by judicious advertisers for the retailers' custom; but there are scores of dealers and manufacturers who, when told that the circulation of a trade paper is 3000 or 4000, are inclined to ridicule its claims as an advertising medium, not knowing that a single edition of a trade paper with even the small circulation of 1000 copies reaches more persons whom they wish to reach than the issue of a daily paper of 100,000 copies. Those who may be surprised at this statement and imagine that our figures are incorrect, may easily convince themselves of their error by referring to any commercial agency reports. To reach the consumer the daily papers are a valuable medium; to reach the retail merchant the trade papers alone cover the field.—London Machinery.

The Monterey's Record.

The report of the Monterey's trial trip has been received and made public at the Naval Office. This official report, signed by Captain Howison as president of the board, says the vessel covered 51 knots on her four hours' full speed test, which is an average of 12½ knots per hour, and this notwithstanding the fuel was poor and the grate bars became clogged with glassy clinkers from the coal. The board says this is a very satisfactory run under the circumstances. The Monterey's boilers and engines were examined immediately after this run and no leaks were found. They were in perfect condition and working smoothly.

Immediately after the maximum speed trial and without stopping her engines the vessel started on her sea trial and was run altogether over 60 hours continuously with all kinds of sea and under all conditions of speed. Her guns were tested with both full and reduced charges. They showed no sign of weakness in any part, the recoil of the 12-inch gun was 44½ inches and 38 for the 10-inch.

The turning engines held the guns and turrets under complete control while loading, the ship at times having a roll of from 4 to 12 degrees. With the sea on the quarter the motion of the ship was regular and easy; with a moderate bow swell she showed the most and quickest action. In the trough of a short, choppy sea she followed the waves closely and shipped a small amount of water on each side. Steering head to wind and sea there was broken water fore and aft, but at no time in sufficient quantities to prevent working the guns and moving about the decks.

There was no defect found in the hull or fittings except some of minor importance, such as a defective capstan or leaky door. There was no defect in the boilers or machinery in any part, the guns and appurtenances worked properly and appeared to be sufficiently strong.

WASTE IN ANTHRACITE MINING.—The commission appointed to investigate the waste in anthracite coal mining in Pennsylvania has made its report. It is stated that at the Parish colliery, where all the small sizes of coal are saved, as high as 19 per cent of the total output of coal goes to the culm bank. This is not culm, but coal. In 1890 and 1891 the Clear Spring Coal Company sent all its buckwheat coal to the culm bank. At some of the oldest collieries the culm bank, with its valuable deposits of coal, is more than half of the total product. In the Panther Creek basin, from 1820 to 1883, 20 per cent more coal went to the culm bank than was marketed. It is estimated that since the commencement of mining 35 per cent of the total product, or 315,700,000 tons of coal and coal dirt, have been sent to the culm banks, which are, therefore, extensive deposits of fuel on the surface of the earth to be bought at a very low price, and which modern inventions in furnaces, blowers and grates have made of great value to manufacturers.

IN the contempt proceedings against S. M. Boyce and A. Westhall for hydraulic mining, Judge Gray of Marysville dismissed the case against the former and found the latter guilty, fining him \$500, which he will probably pay.

THE new camp of Vanderbilt, San Bernardino Co., now has 600 inhabitants. A wagon road from Vanderbilt to Good Springs has been contracted for to haul six tons of ore a day to Needles.

Mechanical Progress.

Boynnton Bicycle Road.

The members of the Thomson Scientific Society of Lynn recently entertained Hon. E. Moody Boynton, who talked to the members about his bicycle railway and its operation by electricity.

The question of questions at the present day is rapid transportation, said Mr. Boynton. Economy is secured by water routes where the cost is seldom more than one mill a ton per mile, but the demand for more rapid transportation seriously threatens the supremacy of the water routes. To-day Boston and the principal cities of Europe and America are as devoid of rapid transit as Egypt at the dawn of civilization. The light engine of Ericsson and Stephenson, which could run as fast as the average train now runs, has been increased in weight until we carry 20 pounds of timber and iron in palace cars and 10 pounds in crowded ordinary cars to every pound of paying weight of passengers carried. On long routes across the continent the weight and waste are so enormous that national railroad bankruptcy is threatened, unless the present extravagant system is changed. But in order to keep the track at high-speed efficiency and to obtain the necessary hoiler and engine power, weight has been increased, rails, bridges and roadbeds made heavier, until all the great thoroughfares are capitalized so heavily that they can be paralleled at one-tenth their cost and entirely swept away by electric rapid transit.

The capital of the railroads of the United States many times exceeds that of the national and savings banks. Any impairment will bring on a financial convulsion and possibly a revolution. I believe that the controllers are conscious that a great change is pending. These roads are banded together and all individual building of steam railroads has ceased. The use of the single rail for the passage of trains on standard gauge railways has been my especial study. We constructed near New York an experimental railroad out of an abandoned standard gauge road so that no practical engineering should go without attention. It was an old surface road elevated for one mile and surface for three-quarters of mile. The curves were so many that it had been abandoned and stage coaches substituted. At an expense of \$100,000 we repaired it and equipped it with my single rail bicycle engines and cars, and in three years we have run 27,000 trains, carried 100,000 passengers safely, smoothly and at three times the speed of standard gauge engines. With an expenditure of five pounds of coal per mile we move three cars containing seats for 324 passengers. I used veneer and steel in the construction of the cars, each of which contains 18 compartments seating six persons each. They are entered from the side like a hack. One brakeman opens and closes the doors of two cars by a lever without leaving his position. Not an accident of any kind has taken place in the three years. These cars are stiffer and stronger than any others, on account of their compartments and special construction with steel and veneers. Where the sheets of the veneer come together in the compartments no strain is observed in stopping the train when running 70 miles an hour. There has been scarcely any wear and tear of the working parts when rounding the sharpest curves. Electricity should be used. If electric energy from coal is between 40 and 50 per cent if applied electrically, and 80 per cent by steam, the difference will be more than made up by the saving in weight. My largest engine contains an eight foot driving wheel with a 14 inch stroke. Nearly two strokes are made to the present ordinary 11-ton engine's one. My first bicycle electric motor car has wheels five feet in diameter, turning on spindles, one at each end of the car, which is sharpened to cleave the atmosphere. The field and armature are in and on the wheel and it can turn the sharpest curve. If a road of sufficient length were completed the first motor could run at the rate of 200 miles per hour.

Smokeless Combustion of Coal in Europe.

Recent reports from Germany convey that the difficulty of burning coal without the production of smoke has been overcome, and that the demonstrations leading to this result have excited much interest among several large enterprises, including the North German Lloyd and the Hamburg American Packet Company, while, it is said, the Vulcan Forges of Stettin have actually adopted the new system. This invention differs from all others which have been employed for the purpose up to the present time, and it is

styled "the automatic and smokeless combustion of powdered coal."

The process is a simple one, says *Invention*. The fuel, instead of being introduced into the fire-box in the ordinary manner, is first reduced to a powder by pulverizers of any construction. In the place of the ordinary hoiler fire-box, there is a combustion chamber in the form of a closed furnace lined with firebrick, and provided with an injector similar in construction to those used in oil-burning furnaces. This chamber has two openings—one on the center line and in the place of the usual furnace fire-door, the other on the opposite side. The orifice of the nozzle is placed in the latter aperture and throws a constant stream of fuel in the chamber. This nozzle is so located that it scatters the powder throughout the whole space of the fire-box. When the powder is once ignited—and it is very readily done by first raising the lining to a high temperature by an open fire—the combustion continues in an intense and regular manner under the action of the current of air which carries it in. This current is regulated once for all by the amount of powder required for the production of the heat led off to the boiler and the evaporation of the weight of steam demanded.

The powder is stored in a box, whence, by means of an ingenious arrangement, the air under pressure carries it to the fire-box. Numerous applications and experience have, according to continental journals, established this practice on the South Eastern railway of Russia and the steam vessels of the Caspian sea.

In the system under consideration, the coal, so that it may be drawn out and carried along by the steam or air under pressure, needs to be finely pulverized, and that is why it is explained that success has been attained in the use of coal which was already finely divided.

The air and fuel are, therefore, intimately mingled in the furnace. It is urged that in this process the combustion of the fuel is complete, for each particle of coal in suspension in the fire-box is in contact with the oxygen required for its consumption, which is thus proved to be a state of affairs far less difficult of attainment than was hitherto considered.

It is also explained that the air entering the combustion chamber may be first heated to a high temperature by utilizing the heat of the escaping gases in the stack. This air may also be mingled with a jet of steam, which decomposes into hydrogen and oxygen, the hydrogen serving by its combustion to assist in the elevation of the fire-box temperatures. By this system the admission of cold air is avoided and a constant temperature can be obtained. It appears that in case of accident the fire can be instantly extinguished by actuating the valve, which cuts off the supply of fuel. High chimneys are no longer a necessity, as the fire-box is operated under a sort of forced draught.

If we can accept the reports issued describing the results obtained, the system must be a valuable discovery. Works situated in the centers of densely populated localities will find obvious advantages in its use. Even if it be less economical than claimed, the very fact of its suppression of smoke should lead to its wide adoption.

Goats for Puddling a Dam.

We recently copied from the *Engineering News* a paragraph describing the use of goats for puddling the reservoir dam at Santa Fe. Mr. J. M. Howells, C. E., writes as follows to the *News* concerning the subject:

"The paper read by Surveyor-General Hobert, before the American Society of Irrigation Engineers, gives the time occupied by the goats in puddling as from 12 M. to 1 P. M. and 5 to 6 P. M. This was correct when the paper was read, for at that time several hundred goats were proposed to be used, and not 115 as mentioned.

"It was subsequently found that as the travel of the goats did not interfere with the teams, it would be more convenient and economical to use a less number of goats and keep them at work all day. As a result of our experience, we find that 115 goats by constant use would do well the puddling for 30 wheel scrapers averaging about 14 cubic feet per load or about 500 feet haul.

"The material was first spread while dumping, next leveled in a 3-inch layer by dragging a beam, next sprinkled with a sprinkling wagon, and then puddled by the goats. The puddling was thoroughly done in this way, and the surface left just rough enough for good joint with the next layer.

"As goats in this arid region are a dry hill-side animal, I feared such a radical change in their habits as keeping their feet muddy all day would bring on foot disease. No lameness had appeared among them up to six weeks ago, and I have had no word of

any since; it seems likely their hardness will carry them through.

"When goats were first put to work they tired easily, and were able to stand it but a part of the day; we learned this was upon account of the scanty range upon which they had fed, having to rely mostly upon browsing the juniper brush. A few days, however, of feed on peas and refuse hay brought back their accustomed good spirits. And after their day's work was over, they would hutt each other around the corral with the enjoyment characteristic of this singularly precocious animal."

Scientific Progress.

Stars of the Milky Way.

A *Sun* reporter recently spent an evening in St. Louis with Prof. E. E. Barnard, of Lick Observatory. Prof. Barnard is the discoverer of sixteen comets, and he bears the reputation of being the keenest of all the eagle-eyed searchers of the heavens. He is yet a young man, and he is enthusiastic in the work he is now pursuing—photographing the Milky Way.

Original investigators are usually very careful to make no statements concerning their work which facts do not fully bear out, and Prof. Barnard was no exception to the rule. When asked how many stars there were in the Milky Way, he replied: "The old text books said the Milky Way probably contained 20,000,000 stars, but I can photograph more than that number in a five minutes' dry-plate exposure. We estimate pretty accurately that the Lick telescope shows 200,000,000 stars. Of course, you know that photography catches stars which the telescope does not reveal. The greatest revelations now coming to astronomers come along the line of stellar and nebular photography. Modern methods in astronomical photography are such as to give us a quite clear delineation of the Milky Way, nebulæ, and comets. Some of the negatives I have in this little case show us the growth and changes of comets and nebulæ in a most satisfactory way."

Prof. Barnard then exhibited three photographs of the comet which he discovered in October. The first showed the nucleus quite diffused and the tail split in two sections. A negative made twenty-four hours later showed the head contracted, the tail shorter, and the sections closer together. Strangely, another photograph forty-eight hours later showed the tail elongated and the head condensed, giving evidence of a growth of many millions of miles in the tail in the two days which elapsed between the photographs.

"How many nebulous groups have you discovered in the Milky Way to date?" he was asked.

"I have been at work on my photographs about two years, and I think I have found forty or fifty groups of nebulosity supposed to belong to the infant stages of world-making, according to the nebular hypothesis."

Prof. Barnard did not like to make an approximate statement of the number of stars in the Milky Way. Finally, however, he said:

"I do not believe I have half finished my photographs, and it will require three years to complete them, for it is tedious labor, which often requires many hours' exposure, at favorable times, aided by a delicate manipulation of fine instruments. At the conclusion of my labors I believe an estimate may be made, and I think these little specks will prove to be say 500 millions of stars. You must know that no known clock-work will move the instruments so as to keep a given star in one position, so the fingers must be used to adjust the camera. Furthermore, we have to wait long for just the proper conditions for this work."

Prof. Barnard's plates are the most complete and satisfactory ever undertaken, for, besides being an eminent and competent observer, he has been a photographer from childhood. Making photographs of the Milky Way interests him more than any other work he has ever undertaken, and the work has been fruitful in unlooked-for directions. It was while doing this labor that he noticed certain displacements and lights which led to the discovery of many comets. The photographs of stars so large that ours is a grain of sand on the infinite shores of matter in comparison do not show larger on his plates than the thousandth of an inch in diameter, while movements of mighty orbs at the appalling velocities of hundreds of miles per second are slower in the telescope than the creeping of the hour hand on a small clock's face.

"Yet a vaster thought," said Prof. Barnard, "is that the Milky Way, thickly studded as it is with giant stars, and re-

splendent with varied lights and magnitudes, show that every star has back of it a luminous background of possibly millions of suns; and the black spaces on my negatives, which presumably show the vault of empty space, in reality represent billions of miles of the universe, which a longer exposure of the plates would probably people with infinite suns, each with its train of planets, surging with the throb of life and responsive to the control of law."—New York Sun.

Earth Currents.

A very interesting phenomenon, and one that has received considerable attention from various experimenters, is that of earth currents. A variety of theories have been advanced as to the cause of these currents, careful study has been made of their nature and strength and the frequency of the intervals at which they manifest themselves, and it has even been proposed to store up their energy for commercial use. J. Kennedy Gibson has made a series of interesting experiments upon the subject on one of the Java-Australian cables. His observations differ in many respects from those made in other quarters of the globe. In all his experiments the diurnal variation seems to be fairly uniform, the times of maxima and minima agreeing in a marked manner. On the Atlantic cables it has been found that there are two complete alternations in 24 hours, while on the Java-Australian cable there appeared to be but one of about 13 hours' duration, while during the remaining period the currents are weak and variable. The slope of earth-current variation does not seem to coincide with that of the tidal lines. Mr. Kennedy is not inclined to accept the hypothesis that the earth-current variations are due to either the sun or the moon individually, but suggests that they are more probably due to the combined influence of the sun and the moon, and are also affected by thermometric and barometric variations.—Electrical World.

Photographing in Colors.

Photographing in colors is now a *fait accompli*. The most successful negatives have been obtained by the Messrs. Lumiere, who employed the method of M. Lippman. "The pictures that you behold in these negatives," said M. Berget, in a recent account of the experiment, "are like aquarelles. Here is a cluster of flowers—roses, violets, jasmies—which appear in their proper colors, their real colors, with all their infinite delicacy of multiple and various tones. Everything is there—the green, the white, the blue, the red, the rose and the violet, with their subtle, velvety hues; everything is there but the fragrance of the flowers. Here, again, is a bit of park scenery, with a sky of exactly rendered blue, with graveled pathways which one distinguishes with perfect clearness from the earth graded for the green sward; here is a ravishing little cottage, all bathed in sunshine—and what sunshine!—and here a vista under the trees, made of sombre greens and light greens, the lights deliciously distributed and the whole view giving the sensation of nature itself." Until the time of exposure is accelerated, portraits in color will not be popular. With the gelatine plate now used, from twenty-five to thirty minutes are required, and there are very few who would care to remain motionless for a half hour in the brightest sunlight to see ourselves as others see us.

ELECTROLYTIC SEPARATIONS.—The London *Electrical Review* gives a short summary of recent papers on this subject. Dorrschach (*Chemiker Zeitung*, v. 16, p. 118) states that from an ammoniacal solution of copper the metal is deposited without contamination, even though silver, bismuth, antimony, arsenic or tin are present; mercury and cadmium, however, may interfere; if the action is too prolonged, nickel, cobalt and tin may be deposited. Smith (*American Chemical Journal*, v. 14, p. 435) states that iridium is not precipitated by the current if there is an excess of phosphoric acid or an alkali phosphate, whereas palladium and platinum separate readily. Smith & Wallace (*Journal Analytical and Applied Chemistry*, v. 6, p. 87), state that in potassium cyanide solutions gold is readily separated from arsenic, molybdenum or osmium, and from wolfram if dissolved in the potassium cyanide, but if dissolved in potash the separation is unsatisfactory; osmium separates readily from cadmium, silver and mercury in a potassium cyanide solution, and cadmium from nickel if potash is present. Rudorf (*Zeitschrift Angewandte Chem.*, 1892, p. 695) gives methods for the separation of various metals. Medicus (*Ber. d. Deutsche Chem. Ges.*) states that lead may be separated accurately and rapidly from galena if

dissolved in hydrochloric acid, then in potash, and precipitated as carbonate by means of carbon dioxide, then dissolved in nitric acid and electrolyzed.

PARKE & LACY, SAN FRANCISCO, CAL.

JOSHUA HENDY MACHINE WORKS.
NO. 51 FREMONT STREET, SAN FRANCISCO, CAL.
BUILDERS OF
"Sensible" Horse-Power Hoisting Whims.
(DAVIS PATENT.)
PRICES REDUCED.
The "Sensible" Hoist is the cheapest and beyond doubt the best in the market. It is built entirely of iron and steel, mounted on a heavy iron base plate, and is therefore very durable and not affected by exposure to climatic influences.
The bevel gear on the drum shaft is loose, and, on hoisting, drives the drum through a friction clutch. This avoids the frequent accidents occurring with other Whims, occasioned by the breaking of the gear teeth when throwing them out of gear. In lowering, the drum is pressed by a powerful screw lever against brake woods at the opposite end. Perfect means of adjustment are provided for the friction clutch and brake blocks.
As the drum is entirely independent from the driving gears the operations of hoisting, dumping bucket and lowering can be performed with the horses in constant motion, a feature not possessed by any other horse hoist in the market, and one that greatly increases the capacity of the machine by avoiding the loss of time due to stopping and starting the horses.
It is very light and compact and very easily taken to pieces for transportation by mules. The cost of erection is very small, two men in half a day being able to put it in place ready for work.
Weight of hoist, 1200 lbs. Total shipping weight, including sweep, levers and sheaves, 1400 lbs.
Circulars giving Capacities and Prices furnished on application.

PLACER AMALGAMATORS
Combined with Steam Shovel or Dredge.
BUCYRUS SYSTEM.
NEW METHOD OF PLACER MINING.
Seves all the Gold. Uses very little Water. Treats large quantities of Low Cost.
—BUILT SOLELY BY THE—
BUCYRUS STEAM SHOVEL AND DREDGE COMPANY,
SOUTH MILWAUKEE, WIS. U. S. A.

BLOWING ENGINE FOR SALE.
Vertical pattern, with balanced steam slide valve gear, steam cylinder 14 in. diameter, air cylinder 40 in. diameter, strokes 24 in. 1 to 100 strokes per minute; engine new.
JAMES LEFFEL & CO., Springfield, Ohio.

THE ORIENTAL GAS ENGINE
IS THE BEST, because combines simplicity of construction with power and economy in space. It can be run with natural or manufactured gas or gasoline at a cost of 20 to 25 cents per horse power per day.
It can be used for pumping purposes, as well as for all purposes where a perfect engine is required, with the advantage of lessening the risk of explosions. No licensed engineer at a high salary needed to operate it.
Send for circulars and prices if a good safe engine is what you need.
The Oriental Lanch is Perfection.
M. A. GRAHAM,
Inventor and Manufacturer,
105 BEALE STREET, SAN FRANCISCO

Electricity.

Electric Propulsion by Accumulators.

The Company of Tramways of Paris and the Department of the Seine has, for a few months past, been operating its Saint Denis lines by means of electricity furnished by accumulators. This new application of electric propulsion by means of accumulators is more important than any of those that have preceded it, says the *Scientific American*. The installation of the Saint Denis depot was made in view of the exploitation of two lines, each about 9250 meters in length. Both start from the cross-roads of Picarde, at Saint Denis, one running to the Madeleine and the other to the Opera house.

The program laid out for the constructors of the motors and the electric accumulators was as follows: To replace, upon the above-mentioned lines, the horse cars by self-moving ones, capable of accommodating 50 passengers and two employees of the company. The mean speed demanded for a full car was 12 kilometers per hour, with the possibility of reaching 16 outside of Paris, and 6 at a minimum upon heavy gradients of from 38 to 40 millimeters per meter. The company, moreover, desired that it should be possible that the electric cars should haul another car. The daily trip estimated for each car was 135 kilometers. Finally, the weight of the accumulators, including all the accessories, was not to exceed 2800 kilogrammes. All these conditions have been fully realized.

The body of the car rests, through the intermedium of rollers, upon two single-axled trucks, carrying bolster pins and connected with each other by a spring coupling that permits the axles to converge on curves and brings them back to parallelism on a straight line. Each axle is actuated by a dynamo-electric machine by means of two sets of gears. The ratio of the angular velocities of the motor and axle is 12 to 1.

The electric motors are bipolar, of the Manchester type, with Gramme ring armatures. The brushes consist of four blocks of carbon placed at right angles with the surface of the collector. Each machine, at a velocity of 1300 revolutions, is capable of developing a power of 10,000 watts under a difference of potential of 200 volts. Under such circumstances, the rendering between the terminals of the dynamo and the axle reaches 73 per cent.

The trucks are provided with the Lemoine winding brake. The battery, which is placed under the seats of the car, consists of 108 elements of 11 plates, contained in ebonite troughs. The plates are 0.2 meter in length, 0.2 meter in width, and 0.006 meter in thickness. The total weight of the active material of each element is 17.5 kilogrammes. These 108 elements are distributed among 12 wooden boxes, 6 on each side of the car. The nine elements of each box are grouped in tension, and the poles of the small batteries thus formed each ends at a strip of copper fixed to one of the lateral sides of the box. Plates of brass, connected with the circuits of the dynamos through a coupling commutator, are mounted by springs upon the wooden supports in the car. The introduction of the boxes between these plates, upon which slide the strips of copper, establishes a connection between the elements of the battery automatically.

The charging of the batteries is done upon benches formed of tarred planks, supported by bricks, from which they are separated by glass insulators. These benches carry spring contacts, similar to those of the axles of the cars. The battery, placed upon the charging bench, has all its elements grouped in tension. The accumulator hall now comprises 24 battery benches, each of which is connected with the distributing board of the charging current by a special circuit containing an amperemeter and an indicator of the direction of the current, and, upon each pole, a circuit breaker and an interrupter. The transfer of the batteries from the benches to the cars is effected through trucks running upon tracks alongside of the benches and the side tracks. The platform of the truck is raised or lowered by means of a screw and winch, so as to bring it exactly to the level of the interior of the car or to that of the charging bench.

The current is furnished to the accumulators by three Desrozier dynamos, each actuated by a Corliss horizontal condensing engine of 125 horse power. These engines are supplied by three semi-tubular boilers. The dynamos, at a velocity of 600 revolutions, furnish a current of 230 amperes under an E. M. F. of 260 volts. They, as well as the circuits of the batteries, are grouped in quantity. The charge is made at a constant po-

tential. The duration of the charging is six hours for a battery that has furnished its whole capacity, which is 230 ampere-hours. The rendering of the batteries in energy is 70 per cent.

The necessities of the exploitation require the possibility of running at various speeds. This desideratum is realized by modifying the coupling of the battery elements. The battery is divided in the car into four parts, or sub-batteries, each including three boxes, say 27 elements in tension, that correspond to a difference of potential, in closed circuit, of about 50 volts. By means of coupling commutator within reach of the motorman, three different couplings may be obtained. The speed of the car varies, in passing from one coupling to another, in the ratio of 1 to 2.

The motors of the cars are normally associated in series, but it is possible, through the commutator, to couple them in quantity so as to obtain a greater speed or to develop a greater stress. The commutator permits, also, of changing the direction of the car by reversing that of the current in the induction circuit of the motors, and, in case of damage, of suppressing one of the motors. A single motor is capable of continuing the service with a slight diminution of speed.

The service of each car is assured by two batteries, that permit of four or five trips being made without recharging. In the latter case, the battery furnishes a motive power for a trip of 55 kilometers. The duration of a trip, including stoppages, is 55 minutes. The weight of the car, complete, is 13,500 kilogrammes, 2600 of which are for the battery and its accessories and 3500 for the passengers. The mean tractive stress is 12 kilogrammes per ton.

Experiments with High-Frequency Discharges.

Mr. A. A. Campbell Swinton, the author of a recent paper in the *Philosophical Magazine*, has succeeded in passing through his body, from hand to hand, sufficient electricity to bring the filament of an ordinary five-candle power 100 volt incandescent lamp very nearly to full incandescence, and found that practically no sensation resulted from the transmission. The apparatus used consisted of a large induction coil coupled to three Leyden jars whose disruptive discharge excited the primary of a high-frequency induction coil. The secondary of this induction coil had its terminals in two brass balls, to which the wires were led through glass tubes filled with oil. One of the terminals may be grasped with impunity, and hardly any sensation is felt; and while thus in contact sparks will pass to any conductor placed near enough. If the free hand, holding a metal rod, be approached to the terminal of an incandescent lamp, as described above, whose other terminal is earthed, the lamp is first filled with phosphorescent light, then sparks pass and the lamp glows, and on making contact the lamp reaches very nearly its full incandescence. The author believes that this result is due, not to the passage of the full normal current through the body (its effect being not felt owing to the exceedingly high frequency), but to the fact that the amperes taken are actually much less, owing to the crowding of the current to the outer surface. The virtual resistance is thus very high and increases the voltage of the lamp; and thus a much smaller current enables the lamp to receive enough energy to produce incandescence. This explanation is confirmed by the fact that while the lamp was glowing sparks passed between its terminals, thus proving that a very high P. D. existed of the order of thousands of volts.

Other curious results were obtained. If the connection from the secondary coil to the lamp were made by a wire, instead of utilizing the body, the lamp reached more than its normal candle-power; thus showing that the body offers resistance to the passage of the current. To estimate this resistance the thumbs of the connecting man were approached, and sparks about one quarter inch long passed, showing a P. D. of some thousand volts. If the hands were brought into contact so as to short circuit the man, the lamp became appreciably brighter. Placing the body in parallel with the lamp between one terminal of the high frequency coil and earth, the lamp was reduced to less than half its brilliancy, the two impedances being apparently about the same. If one terminal of the lamp were connected to the coil and the other were touched by a piece of metal held in the band of the insulated or uninsulated operator, the lamp glowed. The effect in this case is due to the capacity of the gentleman in question. These experiments were made with the other terminal of the high frequency coil free; if it were earthed or touched by another operator, the brilliancy of the lamp was diminished. Again, the in-

candescence was diminished if the lamp was connected directly across the terminals of the lamp; and if the operator occupied a similar position the sensation was quite unbearable. The author concludes, therefore, that capacity has much to do with the results obtained, and that the physiological effects of electric currents are not necessarily proportional to their heating power.

Sampling Works for Sale.

The works are situated at Daggett, Cal., in the Calico Mining District, and on side track of the Atlantic & Pacific Railroad. They contain a first-class 50-horsepower engine and 45-horsepower boiler with ore-crusher and other machinery, Mill Scales, Assaying Outfit, etc., all nearly new. Also upon the premises an office building and a comfortable dwelling-house (portable). The above can be had at a bargain. Apply to JOHN H. GILBERT, 1914 Stockton St., San Francisco.

Useful Information.

Skim Milk for Manufacturing Purposes.

An English scientific journal of recent date directs attention to the utilization of skim milk for manufacturing purposes. Attention was first called to it in connection with the "Rivers Pollution Act." A large firm of cheese makers were in the habit of sending all the whey and skim milk which could not be used for pigs into the nearest river, and the prohibition of this practice has led to invention for its utilization.

One invention is a method for making all kinds of buttons, door knobs, electric lighting furniture, umbrella handles and many small articles from lactite, a substance made from skim milk. In this process the milk is heated to 85° or 88° F., and to every 58 gallons is added about four ounces of rennet. As soon as the milk is coagulated, the curds are washed once in warm water and then put into a masticator, which is warmed to about 150° F. In the masticator should be placed about 2½ pounds of borax, with about four pints of skim milk. When the masticator has been run a short time until the curd is almost converted into a solid mass, about two pounds of starch (preferably arrowroot) are made into a paste with some of the milk or whey, and three ounces of alum are also added, and the whole mass well incorporated.

The masticator is run for about an hour, and then three pounds of acetate of lead dissolved in half a gallon acetic acid are added to the mass, and carefully worked in, and when the mixings have been well made the mass is taken to the hydro-extractor, and then put into a hot press until it is properly set.

A large factory was fitted up near Manchester, England, for the manufacture of lactite, but it is said that up to the present time it is not a financial success. The lactite, when so prepared, will keep for any length of time.

The second process which is being experimented upon is to convert the skim milk or whey into a portable article of food. It is impossible to send skim milk or whey at a profit to distant towns, and some simple process by which farmers could get rid of the water at a small cost, and leave a residue rich in nitrogenous matter, is a thing very much to be desired. Lactoserin, the name given to this product, is prepared in a variety of ways as food for man, cattle and poultry. Roasted it can be used for mixing with cocoa instead of starch.

The manufacture of these products should possess great interest for the farmer, for it will enable him to turn to marketable value what has been too often a waste product. The dry curds are obtained from skim milk in the same way as in the production of cheese by adding rennet. The curds are pressed and ground and then dried in a drying oven. It has been estimated that the cost of manufacturing dry curds will not exceed more than about one farthing a gallon for the skim milk used.

APPRENTICES.—Boys are no longer apprenticed as formerly to a master who takes them into his family and teaches them a trade in all its branches. In the old days the master was responsible, legally and morally, for his apprentice's advancement, worked beside him in the shop, and saw to it that he acquired full and accurate knowledge of his craft. The introduction of machinery and the subdivision of labor have been working together for years to make intimate supervision and instruction of this kind impossible. The master mechanic, instead of presiding over a small shop, and being a master of all branches of his trade, has become, in many instances, the master of merely a single branch of his trade. But whether master of whole or part, he does not work with his men, and can give no personal attention to an apprentice. It has come about, therefore, that boys are hired to do the menial work of the shops, to sweep and clean, run upon errands; and, as part payment for his work, they are permitted to pick up only as much knowledge of the trade as the good nature of the foreman and journeymen will permit. Of system and thoroughness in the knowledge thus picked up there is none. From the menial nature of the employment, self-respecting boys regard it as degrading, and consequently refuse to enter upon it.—June Century.

INSECTS do not breathe through the nose and mouth. Down the body runs two main pipes. These pipes send out branches to right and left like a network, extending to the extremities of the body, even to the ends of the antennæ and to the claws. Each

main tube receives the external air through nine or ten spiracles or breathing holes, placed at intervals along the sides of the body. The spiracles are made water-tight and dust-tight by a strong fringe of hair which completely guards the entrance.

BAROMETER FOR MINES.—Dr. Carlo del Lungo has constructed a barometer of high sensibility, which would be of great use in coal mines. According to a description in the *Rivista Scientifica Industriale*, the apparatus is composed of a vertical tube 20 mm. in interior diameter and about 1 m. in length, the bottom of which is curved in the ordinary manner, the opening at the top, however, being furnished with a steel peg screwed in an iron collar attached to the tube. A long capillary tube, 1 mm. in diameter, is fixed at right angles on the large tube, a little above the curved part, and terminating in an open receptacle. The quantity of mercury is regulated so that the meniscus of mercury presented itself in the middle of the capillary tube. The slightest difference of atmospheric pressure will cause the mercury to rise and act on the capillary column. A fall of pressure is indicated by the inverse movement of the column. In this way the increase or decrease of the mercury in the large tube is augmented according to the section of the tubes, and in this case as 400 is to 1. A variation of 1.400 of a millimeter can therefore be noted. If the variation in pressure become great enough to cause the meniscus to leave the capillary tube, that may be remedied by screwing or unscrewing the upper peg.

THE MOVING SIDEWALK AT CHICAGO. For those who come by the lake route, and for others who prefer to sail on land, there is the movable sidewalk, seating 40,000, and extending out on the great pier 2000 feet into the lake. The view of the grounds from the end of the pier is superb, and, as one can ride as long as the fancy dictates for one 5-cent fare, it is deservedly popular. The construction of the moving sidewalk with its endless chain of seats was not alone for fun, but fact, and to demonstrate its wonderful possibilities for the transportation of great masses of people. The line, which is operated by electricity, has a capacity of 240,000 passengers per hour. There are three endless platforms, forming a loop at each end. The first is stationary, the second moves at three miles an hour, and upon it one steps in a natural walk, but without experiencing any jar or shock; from this he steps to the third platform, moving three miles faster than the second, or at a total of six miles per hour. This third platform is entirely filled with cross seats. The moving platforms are carried on ordinary railway wheels and track, and constitute one of the most interesting attractions on the grounds.—Review of Reviews.

JOSHUA HENDY MACHINE WORKS, 51 Fremont St., San Francisco.

THE BLASDEL CONCENTRATING BELT COMPANY.

We are now having our new Improved Concentrating Belt manufactured in San Francisco. We keep always on hand Belts suitable for the Triumph and Frue machines, but can make any length or width desired. The advantages of these belts over any others will be readily seen by practical millmen. First, the flanges or edges of our belt stand at an acute angle inclining toward the center, and therefore readily conform to the change of direction while passing over the end rollers; thus the vibration and loss caused by the frequent breaking of the flanges of the old style belt is practically done away with. Again, our belts, at intervals of two to four feet, have a very slight rifled surface for the space of three inches, which tends to equalize the pulp on the belt, and prevents it from banking on the sides and forming channels through the center. These slight rifles also save very fine sulphur and the quicksilver that would otherwise escape with the tailings from a belt, the surface of which is entirely smooth. We can safely say that it is a better concentrator belt than has ever been manufactured. It will last much longer and will handle more pulp. We also manufacture smooth belts with same flanges when desired.

MESSRS. ADAMS & CARTER, 132 Market Street, San Francisco, Cal.—GENTLEMEN: After a continuous trial of different concentrators comprising the Frue Vanner, the "Holland," "Paradox," "Triumph" and the "Woodbury" concentrators, extending over several months, we find that we prefer the Frue Vanner, as it is easier of adjustment, runs smoother, has less wear and tear, and—having a positive travel—gives less trouble than the other more complicated and ever changing machines now in use here. The Frue Vanner not only saves cleaner concentrate, but has less loss in the tailings, and is in several ways preferable to the other concentrators here.

I am, my Dear Sirs, Yours faithfully,
 S. HARRIS, Manager.

Mining Summary.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ASSAYS FROM THE BELL WETHER.—*Ledger*, June 16: An assay has just been made in San Francisco of some quartz taken from the Bell Wether mine of this place, owned by S. W. Bright. Ore taken from the south drift assayed \$3.50 per ton in free gold, while the sulphurets showed \$60; rock from the north drift assayed \$8, and the sulphurets \$78; from the crosscut \$12, and the sulphurets \$95, making an average of \$8 for the ore and \$75 for the sulphurets. These samples of rock were selected by San Francisco parties who are interested in the mine to the extent that they would like to purchase it, and are talking about it. The points in the north and south drifts from which samples were taken are about 200 feet apart. The average width of the ledge is from 35 to 40 feet. All who have examined it say it is the "biggest thing" ever struck in Amador county.

THE ARGONAUT.—Articles of incorporation of the Argonaut Mining Co. were filed in the county clerk's office last Monday, the incorporators being W. F. Detert, J. B. Francis, H. Eudy, B. Taylor and C. Berger. They are organizing a company with 200,000 shares of stock, at a par value of \$5, for the purpose of working the Pioneer property. The promoters of the company have already placed 200,000 shares and could place more if they desired. The proceeds are to be used in developing the property. It is probable that preparation for sinking a deep shaft will be made within 30 days.

THE BRIGHT MINE INCORPORATED.—The San Francisco parties who have bonded the Bright mine of Jackson have incorporated under the name of the Bright Mining and Milling Company, with G. W. Osborn as President, G. W. Osborn, Jr., as secretary, and P. H. Kane as treasurer. Three miners were put to work last Monday crosscutting on the surface. Superintendent A. V. Oliver will arrive this evening and immediately make a location for a shaft. This company means business and will thoroughly develop the property, with every indication of opening up a fine mine.

NOTES.—J. H. Tibbitts, superintendent of the Albany, remarked to a group of mining men in the National hotel the other evening that Jackson had a great mining future; that the dividends of the famous Kennedy were now attracting capitalists, and he believed that the time was near when, from the Kennedy to the Mokelumne river on the main contact, a line of hoisting works would be in operation and several good properties opened. At the Hardenberg the shaft is being advanced below the 600-foot level at the rate of 15 feet per week, with very encouraging prospects in the bottom. The water pipe of the old line from the Zeile reservoir to the mill is being taken up, and that which is of any value is being repaired and relaid. At the Albany both tunnels are being advanced across the country rock, with occasional stringers of quartz being cut, giving low assays. At the Farrell bids have just been closed for an additional 100 feet. The work was let to the original contractors. A fire was started Wednesday in the furnace of the Zeile chlorination works.

Butte.

THE GOLO BANK.—*Marysville Democrat*, June 10: Thursday last the Democrat mentioned the fact that W. W. Stow had on that day made proof and payment in the United Land Office on land embraced in the claim owned by him near Forbestown, known as the Gold Bank quartz mine. This property is located a short distance north of the Yuba county line, and about four miles from Brownsville. There are several other valuable mines located in this same range, among which is the R. C. mine near Brownsville, now being worked under the superintendency of J. C. Cambell. The Gold Bank mine is in charge of H. P. Stow, a son of W. W. Stow, of San Francisco, who is now having erected at Forbestown a fine residence which will cost several thousand dollars. Mr. Stow employs an average of 85 men in the conduct of the mine, and the wages paid are three dollars a day, the men receiving their pay every Saturday night if desired. Including lumber, labor, timber and wood, the sum expended monthly in the conduct of the Gold Bank mine is \$8000, which of itself is a big item in a small place like Forbestown. This mine is a very valuable piece of property, yielding, from one ledge, copper, silver and gold, the sulphates being treated by the roasting process to secure all of the precious metal. The mine at present, with its 20 stamps, produces not less than \$200 daily, or from \$35,000 to \$40,000 per month, with an apparent endless amount of gold-bearing quartz. The hoisting works and house were burned about two months ago, and were at once replaced with a better plant, and now, taking the whole work from the timbering of the incline to the plates for saving the gold, the roasting and assaying departments all present neatness and are composed of the latest and best to be had for the money. The Shakespeare mine near the Gold Bank is of about the same class of ore and is paying regularly. This mine, under the new management is being equipped with new and improved machinery, which, when completed, will, it is believed, cause an output equal in amount to that of the Gold Bank. There are other mines being worked in that vicinity and several prospecting for the precious metal, and in all there are probably 250 men employed.

El Dorado.

WILDMAN.—*Placer Herald*, June 17: The Wildman mine, formerly known as the Taylor mine, just across the river in El Dorado county, is paying big. Last month's cleanup was over a hundred pounds of clean amalgam. About 40 men are at work. The property is lighted throughout by electricity. Some handsome specimens have been taken lately from the Revenge mine, near Greenwood. This mine has been condemned for about five years. Those working it at present expect to strike something rich. The Wildman Mining Company, which recently purchased a claim from Ed Polifka and others situated on the American river, about two miles from Michigan Bluff, has completed the survey for a road from Georgetown to the

river. The company, we understand, will erect a 40-stamp mill.

Humboldt.

THE JANES CREEK MINE.—*Blue Lake Advocate*, June 13: If one may judge from appearances the outlook for development of the Anger Iron mine on Arcata bottom is bright. Mr. Charles Fulmore, who had some months ago secured a lease of the mineral land (a tract of 240 acres) for the purpose of developing it, has filed a relinquishment of it, and a few days ago Mr. Frank Morton, a representative of the Pittsburgh Iron Co., of Pennsylvania, after investigation of the vein of ore, leased, in the name of the company, 40 acres of land. It is announced that near the site of the Jolly Giant mill a smelter will be erected, so that the expense of shipment of ore to San Francisco may be obviated. The expectation is that work will go right on now in a satisfactory way.

ON THE KLAMATH.—*Blue Lake Advocate*, June 17: William Young, one of the stockholders in the Morick Hill mine, on the Klamath, has disposed of his interest to the rest of the company, as we learn from Mr. James Graham, who came down the first of the week from his ranch on Klamath Bluff. Mr. Graham tells us that the ditch for conveyance of water from Cappel creek has been completed, and that the force at present there are busy prospecting. The ditch, it seems, does not bring to the claim the volume of water needed, but if the result of their prospecting shall be satisfactory they expect to widen it or deepen it, or both. The circumstance that they have seen proper to buy Mr. Young's interest in the mine Mr. Graham is disposed to regard as an indication that they have faith in it. This mine was located three or four years ago by R. W. Miller, J. Lamb, William Young and a gentleman named Mulkey, but they soon discovered that they were too poor to do anything with it. They had a water privilege available ten months of the year, but to bring water four miles they found a big undertaking. Yet they kept on renewing until they had exhausted all their rights and then bonded mine and water right to A. B. Campbell, of Crescent City, and J. Miller, Mr. Hotchkiss and Mr. Guerne, of Healdsburg, with the understanding that they should have a specified time to put water on.

Mono.

NO MEN WANTED.—*Bodie Miner*, June 17: Several miners have been coming to Bodie lately from other camps. To those who have any intention of heading this way in the expectation of getting work, we will say that such a trip will be but a waste of time and money, as they will only meet with disappointment. Things at present are at a standstill, and when the Standard resumes operations there will be more than enough men right in town to make up the necessary force.

Nevada.

BONDED A MINE.—*Transcript*, June 12: R. R. Colgate, of Colgate & Co., the large toilet-soap manufacturers and perfumers of New York, who has been in this city several days, left for his home yesterday. During his stay here he obtained a bond on the Coan quartz mine, situated on Indian Flat, and arranged to have the same worked. A 7-inch pump will be put in at once, and the shaft sunk deeper. Work was begun this morning.

TO HYDRAULIC AT COLUMBIA HILL.—*Nevada Transcript*, June 17: It is currently reported today that the Eureka Lake and Yuba Canal Water and Mining Co. will next week apply for a license to resume work on its rich hydraulic mines at Columbia Hill. Disinterested parties who have examined the works are of the positive opinion that the Debris Commissioners will not hesitate to grant the license after they have thoroughly examined the works, as they are such that will strictly comply with the law. This famous mine has a magnificent impounding dam, and when it was worked, the water below the dam showed hardly any discoloration. By misrepresentation on the part of the valleties, the parties working the mine under a lease were enjoined. Rather than fight the valleties, they concluded to close down and wait until they could ask for a license from the Debris Commissioners. If a license is granted, the upper part of the county will soon resume some of its pristine glory, as it means the employment, directly and indirectly, of something like a hundred men. If the Eureka Lake Co. is granted a license, other companies will doubtless construct the proper dams and ask for a license. Should it be shown to the satisfaction of the Debris Commissioners that these mines can take care of their debris, the licenses will probably be granted. The starting up of three or four big hydraulic mines on the Ridge would give new life to that section and inaugurate an era of prosperity for the whole county. Said a gentleman to the *Transcript* reporter: "I cannot see how the Debris Commissioners, who are all fair men and will do their duty as they understand it, can refuse the Eureka Lake Co. the license which they will ask for, for everything has been done to comply with the Caminetti bill, and if that mine cannot be worked in its present condition, we cannot hope of ever seeing any more hydraulicking in this State."

Placer.

NOTES.—*Placer Herald*, June 17: The Mayflower is paying as well at the present time as it ever did before. The Sunny South and Paragon are paying exceedingly well. L. Remler, of Forest Hill, has commenced on his timber contract for the Sunny South mine. The Big Spring mine, adjoining the Dardanelles, is paying \$5 to \$6 to the pan. The Gray Eagle is still shut down. We understand it will be opened again soon. The World's Fair Mining Co., which has a mine just above Mammoth Bar, are about ready for work. They are getting out some heavy timbers to be used for the water-wheels. Work commenced Thursday at the French Hill claim one mile below Spanish Diggings, in Hoboken canyon.

Shasta.

LOWER SPRINGS.—*Cor. Shasta Courier*, June 17: Mr. Connors has made another big strike in one of his locations. The ledge is large, and, although not a color of gold could be seen in it, 40 pounds of the ore yielded \$3.50 when crushed in a hand mortar. The Mill, Gold Coin and Bonanza ledges are improving all the time, and are, as Mr. Connors says, bonanzas indeed. Spraggins is taking out some fine ore. The ledge is widening out, and Tom feels bigly pleased with the Sally Ann. The Bulkhead has been closed down. The owners will lay a

track and put in a car. The last rock taken out showed considerable free gold. The White Oak mines are still idle. Your correspondent was informed that Mr. Conant will dispose of them at auction before long. The Hartman Mining Co. is pushing work on its mill at Middle Creek.

CHLORINATING PLANT.—*Shasta Democrat*, June 21: The Gladstone Mining Co. is putting up a chlorinating plant at the mine, so we are informed. Al Donahue and partner, Mr. Vincent, yesterday sold a third interest in the Caledonian mine, near Churntown, to a gentleman named Nichols of San Francisco. We are informed that another milling plant, which will work custom ore, will soon be erected on Clear Creek, Igo. The machinery for the plant has been purchased, and men are at work excavating the mill-site. J. J. Kerneen has purchased the machinery of the Mad Ox mine, near Stella, formerly owned by J. B. Haggin of San Francisco, and will remove it to the Hidden Treasure mine on Iron Mountain, where he intends erecting a ten-stamp mill. C. E. Brown, secretary of the Miners' Association, spent several days last week in French Gulch district, collecting samples of ores for the mineral exhibit at the association's rooms. He and Major Lyons are building up a fine exhibit of Shasta county ores. Bell & Scranton have resumed work on the Summit mine at Sunny Hill, and have discovered another rich ore chute, from which they are taking shipping ore that averages \$600 a ton. They have shipped many thousands of dollars worth of ore from this mine in the past three years. We hear that Jim Campbell has struck a fine gold prospect high up on the mountain on the South Fork of Squaw Creek. It is a claim Jim has held for several years. He has run a short tunnel on the vein, which is four to five feet wide, and the quartz prospects way up in free gold. Jim is a rustler and hard worker, and deserves to find something good. Mr. Parker, the gentleman who has been developing the Crown Point mine on the southwest side of Muleton Mountain, is about to close a sale of his interest in the property to a Sacramento company for \$25,000. Mr. Parker expects the deal will be closed next week. He says the new company will immediately erect a milling plant on the mine. The Sacramento people who bought a mine from Ezra Thomas and paid \$5000 down two weeks ago, came up a few days ago and went out to the mine. The property is located on Pit river, above Copper City, about four miles from Brock's place. It is a claim a prospector named Norris located three years ago, and after doing some work on it abandoned it a year ago. Last fall Thomas went to the mine and discovered a big chimney of rich gold ore. Mr. Parker, of the Crown Point mine, placed the mine for Thomas. The ten-stamp mill on the Tellurium at Middle Creek is hammering away on ore from the Cleveland, and is doing good work. On account of the scarcity of water, the mill runs only during the day. Mr. Scherer is running a tunnel on the Schafer, also is driving ahead on the Tellurium and Cleveland. He is putting in a small plant to test the cyanide process for treating the Tellurium ore, and, if it proves the proper thing, a plant sufficient to handle the product of the mill will be put in.

Sierra.

RISING SUN.—*Mt. Messenger*, June 17: The Rising Sun Mining Co., near Allgaby, is preparing to put in an electric plant. The dynamo will be placed on the Middle Yuba to generate the power to be transmitted by wire to Kanaka Creek, about 2½ miles, where the mill will be built. Mr. Gifford of Los Angeles is up inspecting the Comet quartz mining property, situated in Jim Crow canyon. We learn that the chances are promising for the company he represents to take hold of this property and develop it. Some \$10,000 or \$12,000 will be expended.

Siskiyou.

BLUE GRAVEL.—*Yreka Journal*, June 21: The Greenhorn blue gravel mine is again at work. They have their splendid new pump at work, and it handles the water with ease. The old pump was too small for the volume of water that was entering the shaft at this season. The hoisting works have been remodeled and simplified and everything is put in fine shape. A large force of men will be put to work at once, and, if no unforeseen mishap occurs, the work will proceed without any interruption, as a large amount of gravel is now in sight that will pay well. It more than paid expenses in opening, and it will now pay a fine dividend. The middle or best paying part of the channel has not yet been reached. We understand that the company intends to sink a new shaft soon and put in a new hoisting plant soon and work it more extensively. There are a number of acres that are known to contain fine auriferous gravel that will pay handsomely for working. The old shaft, above the one at which they are at work now, paid more than \$20 a day to the man, but it caved in on them and they were obliged to abandon it. That same ground will soon be opened up again.

AT SAWYER'S BAR.—J. Sallee of Sawyer's Bar stopped over night in Yreka last night while en route to San Francisco. He had with him a fine lot of quartz and gold specimens. He and other parties had just recently discovered a fine ledge near Sawyer's Bar, and these specimens were taken from it. We understand that they panned out \$7500 around the ledge in one day. The results of mining are singular sometimes. Clark and Colson have been working what is known as the Uncle Sam mine on the Middle Fork of Humboldt, and, after going down some distance, the "pay quartz" disappeared, but work was continued. Last week they were about to shut down and quit work, as they thought it futile to continue work as there were no prospects of "pay"; but just then at a depth of 125 feet they opened a two-foot ledge of very rich quartz. Samples were shown at Judge Warren's office, and they were brilliant with gold. The mine is owned by San Francisco parties—Thomas Ager, Major Gillis and others. The samples of quartz exhibited here were sent to San Francisco to show what Humboldt could turn out. We expect to hear of many big finds in Humboldt before the summer is over.

Trinity.

FINE CLEAN-UP.—*Trinity Journal*, June 17: We learn from Wm. Vollmers, proprietor of the Trinity Center Hotel, who was in town this week, that a fine clean-up was made at the Strode mine last Saturday. From 30-bours' run with a cannon-ball mill, in which time four and a quarter tons of quartz were crushed 60 ounces were taken from the plates. The rest of the mill was not cleaned up. The mine

is about six miles from Trinity Center on Hostetter gulch. Mr. Strode has sunk on the ledge 230 feet. The ledge runs from 18 inches to 4 feet in width.

NEW RIVER NEWS.—We have just recovered from one of the severest winters known in the history of our camp. During the past two weeks the weather has been very beautiful. Clements & Ladd started a number of men to work at washing the Mountain Boomer mine about two weeks ago. They expect to realize thousands of dollars in a few months time this summer. They run down about 100 tons of dirt every day, which prospects from 75 cents to \$2.50 a ton. F. J. Ladd has five men engaged at taking out ore in the Toughnut. No doubt Mr. Ladd will keep his quartz mill, which he started to run yesterday, busy all summer and fall. Thos. Pharis of Eureka is running the Excelsior mill for Messrs. Leas and Nicholson. They had a large quantity of ore packed recently, which will keep the mill in motion quite a while. The Great English Consolidated Ridgeway Co. has failed to proceed with the necessary prospecting, or further development, which Mr. Stevenson, the San Francisco mining expert, advised them to do. We have heard through very good authority that Mr. Stevenson's general report of the Ridgeway ledge has been a very favorable one. Therefore, we fail to see why the company did not "appropriate" a few more thousand of Her Majesty's so-called royal pounds and sovereigns, and feel satisfied, without a doubt, that they were justified in abandoning the mine and mill. They have quit work without half completing the work which they knew, when they started, would be necessary for them to accomplish before they found a ledge. Miller and Son are quite busy washing the dumps on the Sherwood mine. They are also running their quartz mill and crushing custom rock at present. Yocum & Son are working the New Moon. They have just made a clean-up from that mine which we hear is quite satisfactory.

HYDRAULIC MINES.—*Shasta Democrat*, June 21: Mr. D. R. McCleary, one of the owners of the Bloss & McCleary hydraulic mine at Trinity Center, was in town a couple of days last week. He informed us that the French people who bought the Ward-Loverage mine at Weaverville are negotiating for the Bloss & McCleary mine. This is considered to be one of the best hydraulic mines on the coast. Jack Strode, of Whiskeytown, has the making of a promising mine on Hostetter gulch, four miles up the Trinity river from Trinity Center. Last week, from a 30-bours' run with a cannon-ball mill, crushing a little over four tons of ore, he cleaned up 60 ounces of amalgam from the plates. The rest of the mill was not cleaned up. Mr. Strode has sunk on the ledge 230 feet. It runs from 18 inches to 4 feet in width.

GOLO NOTES.—*Prescott Courier*, June 15: George Ridenour is in from his Delta mine, a short distance below Harlan's Camp, near Prescott. He brings with him some fine free-gold specimens. He has worked this mine for the past 12 years and made regular shipments of ore from it, the ore always holding well up to its average of 175 ounces silver and one ounce gold per ton. He has now 12 tons of ore on the dump. The pay streak is about 14 inches in width. The mine is developed by two tunnels of 90 feet each, one of 75 feet, three shafts, one of 60 feet, one of 56 feet and one of 45 feet. The fact of a man working one mine for 12 years with paying results speaks well for this vicinity as a mining section. Many a sack of gold dust and bar of bullion finds its way into Prescott, under cover of night and over obscure trails in the mountains, no public record of which is ever made. The reason of this secrecy is that miners fear to tempt the cupidity of men who might develop into highwaymen. Hence any accurate statement of our great gold output is impossible to get at. Every now and then the *Courier* accidentally runs on to a man who looks like he never had a dollar in his life, but who really is loaded down with gold bullion running into the thousands of dollars, and the invariable request is: "Please don't say anything about it." This is bad for the country, for only by making our riches known to the world will we prosper. G. W. Hull is in from Jerome, and says the general public have little idea of the extent of the great mines of the United Copper Co. at that point, which are among the largest, if not the largest, paying ore deposits known in the world. First theories were that the ore was a blanket deposit of no great depth, but after the workings of years, during which hundreds of feet have been sunk, there is now more rich ore in sight than ever. In fact, the workings are nearly all in ore. The mines offer a fine market for the products of the tributary ranches, and the prosperous and growing town of Jerome has sprung up around them.

NEW RIVER.—*Blue Lake Advocate*, June 13: Justice G. W. B. Yocum reached Blue Lake Saturday from the New River country. Our informant states that there are about 40 men in camp, and that the Sherwood, Excelsior, Toughnut and Boomer mines are in operation. The Toughnut in particular is accumulating some good ore. When the water gives out on the Boomer the force of men will be employed on the Hardtack. "Last year," remarked the Judge, "Hardtack people took out of the dump \$2000 in the space of two months, and five or six years ago the owners of the Hardtack took out some ore that assayed over \$80 a ton. You must understand that the New River mines are spotted. Sometimes one will strike a lead that pans out fine, and then again one will work a long time without results." Taken all around, the winter was severe at New River. Lots of snow fell in that country. There were ten feet of snow at the Mary Blaine mine when he came down, and he says he shouldn't be surprised if it is 40 or 50 feet in some places about the mine. A great deal of gold has been taken out of the Sherwood, Judge Yocum thinks, but how much money has been cleared is quite another question. The Ridgeway is not running. On Pony Creek, Uncle Steve Noble and sons have been at work and are doing quite well. The Judge himself is at work on a new claim which prospects well.

Yuba.

SMARTSVILLE IS WAITING.—*Marysville Democrat*, June 21: Representatives of the Democrat paid a flying visit to that once famed town, Smartsville, on last Sunday. They found the law-abiding citizens of that place at present living in hopes. They have, in conformity with the law, ceased all mining operations and now await patiently the action of the Caminetti Commission. It is the general opinion among the residents, young and old,

that the mines at Smartsville will be the very first to commence operations under the new law. Their claims are so situated that they can easily meet the provisions of the Act and carry on a legal system of mining—at least they feel confident that they can convince the Commission that they have the correct dumping-ground for the tailings that will result from the washing-down of the immense banks that now stand sentinel-like over Timbuctoo and Sucker Flat. If the hopes of these honest people are realized, Smartsville will again become the lively camp that it has been written in past years. The horny-fisted miner of the day and night shift will again seek his old haunts and Smartsville will boom. The father will again be seen to move from his humble cottage at early morn with lunch-bucket in hand, and, followed by an encouraging smile from a loving wife, enter into a lawful pursuit—so recognized by the Government. Smartsville at present contains many young men who have no steady occupation. With the new order of things they will be encouraged to habits of industry and enterprise; Smartsville will find new business houses springing up, with her young men at the helm. The deserted nooks about Sucker Flat and Timbuctoo will take on new life and the schools will require several more rows of desks, with an extra teacher or two. A railroad will connect the lively mining camp with Marysville and surrounding towns, and in a few years the surrounding country will not be recognized as the same. The perplexing question that has held this section at a standstill for a number of years will soon be decided, and Smartsville's visitors of last Sunday feel that the agitation has worked great benefits, so far as Smartsville is concerned.

NEVADA.

Washoe District.

CON. CAL. & VA. MINE.—*Virginia Chronicle*, June 17: 1500 level—No advancement has been made during the week in the openings leading from the southwest drift, 75 feet above the sill floor of this level, but in working along the first part of the drift run west from the end of the southwest drift we have extracted a few tons of ore which assays \$21 per ton. 1650 level—Have continued making necessary repairs to the drifts on the sill floor of this level and to extract some ore in working west from the old stopes, on the third floor, operating through the upraise, No. 6 carried up from the main northwest drift. Also from the old stopes in working north from the crosscut run west from the northwest drift. The crosscut run east from the drift run south from the end of crosscut run east from a point 60 feet up in the upraise which was started from the drift run west from these north workings, 27 feet above the sill floor of this level, has been advanced 36 feet; total length 91 feet, continuing in porphyry and quartz showing some value. Have continued to extract some ore of average quality in working on the north and south sides of the drift run east (at a point 20 feet down) from the winze which was sunk from the crosscut run west from the main northwest drift. The drift running south from this winze at a point 22 feet down has been extended 20 feet; total length 80 feet; showing some bunches of ore, and we are preparing to stop at this point. Have extracted during the week from all parts of the mine 277 cars of ore about 270 tons, the average assay value of which per car sample was \$36.20 per ton. Have shipped to the Morgan mill 91 1840-2000 tons. The mill is expected to commence crushing to-day, the 17th inst.

OPHIR—1565 level—The crosscut running east from the winze station on the sill floor of this level has been extended during the week 31 feet; total length 52 feet; continuing in a formation of porphyry, clay and quartz, which carries a low assay value. Have continued the work of making the necessary repairs in the shaft, being joint work with the Mexican company.

MEXICAN—On the 1565 level—West crosscut No. 2 from the north drift from east crosscut from the bottom of the winze, sunk from the 1455 level down to this level has been stopped. From this same north drift, at a point 409 feet in, an east crosscut was started and has been advanced 15 feet, in a porphyry formation. Have continued the work of making the necessary repairs in the shaft, being joint work with the Ophir company.

UTAH—340 level—The north drift from west crosscut No. 3, at a point 100 feet from its mouth, has been extended 14 feet; total length 21 feet; face in quartzite, clay and porphyry formation of very low assay value.

SIERRA NEVADA—The intermediate tunnel on Cedar Hill has been advanced during the week 16 feet, making the total length 402 feet; the face is in porphyry and streaks of quartz. The joint Sierra Nevada and Union west drift, 900 level, has been advanced 20 feet, making the total distance west of the joint shaft 3267 feet; the face is in hard porphyry and small seams of quartz.

UNION SHAFT—The joint Sierra Nevada and Union west drift, 900 level has been advanced the past week 20 feet, making the total distance west of the shaft 3267 feet; the face is in hard porphyry and small seams of quartz.

ANDES—On 420 level, south drift from east crosscut No. 1 north, has been advanced 15 feet; total length 27 feet; formation quartz of very low value.

GOULD & CURRY—200 level—West crosscut No. 5, started in northwest drift, 432 feet from main west drift, has been advanced 82 feet, passing through hard porphyry; total length 511 feet. Suro tunnel level—The joint east crosscut from northeast drift has been advanced 18 feet during the week; total length 26 feet; face in porphyry and vein matter.

BEST & BELCHER—200 level—West crosscut No. 2, started in northwest drift, 230 feet from our south line, has been advanced 12 feet, and work discontinued; total length 155 feet; face in hard porphyry. 900 level—The southwest drift started from west crosscut No. 3, 20 feet from top of upraise No. 1 from 1000 level, has been advanced 15 feet; total length 142 feet; face in hard porphyry. Suro tunnel level—The joint east crosscut from northeast drift has been advanced 18 feet during the week; total length 26 feet; face in porphyry and vein matter.

HALE & NORCROSS—On 900 level have completed repairs to the station and to-day started a new south drift, east of the ledge on this level. 1100 level—Are retimbering the main working station

preparatory to starting a new south drift on this level. 1800 level—Advanced the upraise in west crosscut on south boundary 9 feet; total height 75 feet. As it failed to show anything of value, work was stopped on it on the 13th inst. No further work will be done in this upraise. Main shaft—We continue retimbering above the 1300 level, and are repairing main incline where necessary.

POTOSI—The south drift, 35 feet west of the main shaft on the 850 level, is out 66 feet; face is in porphyry. The south drift 200 feet east of Potosi winze, 930 level, is out 43 feet, following four feet of low-grade quartz. The north drift, opposite the last-named drift, is out 125 feet; face in quartz and porphyry, some of which gives good assays. The raise from the north drift, 100 feet north of east crosscut, 930 level, is up 29 feet on the slope; the top shows two feet of good ore. The north raise from the 1000 level is connected with north drift on the 930 level, at a point 100 feet north of east crosscut opposite Potosi winze. In the north raise from the 1000 level, are opening a station 50 feet below the 930 level. The south stope is yielding the usual amount of fair-grade ore. Extracted and sent to the Nevada mill the past week 652 tons and 1500 pounds of ore from the 550, 1000 and 1150 levels. Milled during the week 670 tons. On hand at mill 163 tons and 250 pounds. Average battery assays, \$24.92; average car sample assays, \$28.72; shipped to the U. S. Mint, Carson, 377 pounds crude bullion.

CHOLLAR—Are making repairs to the drift on the 450 level, and repairing the station on the 850 level. The north drift from the east crosscut near the south line, 930 level, is out 54 feet, following a streak of clay and vein matter.

OCCIDENTAL—We continue to extract some ore of fair quality from the 650 level. The upraise from south drift, 650 level, is up 21 feet; top in quartz and porphyry. Crosscut No. 3 from Zedig drift, Suro tunnel level, has been extended 11 feet; face in quartz and porphyry.

Ferguson District.

CAMP NOTES.—*Pioche Record*, June 15: Four teams loaded ore from the April Fool Saturday. The Snowflake, owned by C. E. Goodrich and others, is looking well under development work. The Short mine, owned by Nesbitt Bros., is looking better as development progresses. Two men are working in it. Work on the Magnolia still goes on. They are sinking and drifting on the No. 1 shaft. It looks better now than it did six months ago. The Little Emma is looking better than it has for some time. The ledge is reported to be five feet wide. About 20 tons of high-grade ore is on the dump that will pay to ship. The ledge in the Monitor is 24 feet wide, and is said to carry clear across the face ore averaging 50 to the ton in gold. Teams are wanted to haul the ore to Millford. C. R. Crandall came in from Vanderhilt Sunday. He reports that place pretty lively. There are about 75 men working in New York and 25 in Vanderhilt districts. Potatoes are selling for five cents a pound and water for three cents per gallon. The bins at the April Fool are full of ore, and the boys are now piling the ore upon the dump. They would like to employ some teams, as they desire to make more shipments to Salt Lake. There are two carloads of ore now in the bins and plenty more in sight.

Silver Peak District.

MAY BE SOLD.—*Silver State*, June 16: An English company has in contemplation the purchase of a group of mines at Silver Peak, Esmeralda county. The price asked for the property is \$750,000, and if the sale is consummated it will require \$500,000 more to get water to the mines. It is hoped that satisfactory arrangements can be reached, as it will create new life in that section of the country.

White Horse District.

A RICH DISTRICT.—*Reno Gazette*, June 15: News from the White Horse mining district, eight miles north of Wadsworth, is very encouraging, all the assays reported going from \$100 to \$350 in gold, and there is much excitement. The ledge has been traced for a distance of four miles. The specimens shown by those who have visited the camp are very rich. Over 25 locations have already been made. The ledge is gold-bearing and promises to bring this section into prominent notice in a short time.

ALASKA.

BALD EAGLE GROUP.—*Juneau Record*, June 1: Mr. Keller, M. E., this week chartered the steamer Seoloin and took down men and supplies to commence work on the Bald Eagle group of claims at Sum Dum bay. A sale has been pending on these mines for some time past, but we are not informed whether such sale has been consummated yet or not. According to all reports it is a fine piece of property, and we would be glad to see a man with the reputation of Mr. Keller secure it. The company he represents has unlimited means, and, should they take hold of it, will open it up and undoubtedly place another paying mine to Alaska's credit. This would also entitle owners of other mining properties in that district to commence development work, and as there are a number of fine surface prospects showing, time and development ought to bring to light other valuable mines. Wm. M. Bennett will have his mill running in a short time on the Aurora mine, in Silver Bow basin. This property has made a good showing, and with a mill cannot fail to yield dividends.

ARIZONA.

A BIG STAMP MILL.—*Phoenix Gazette*, June 18: W. B. Gillingham, superintendent of the Phoenix mine, has returned from San Francisco and New York, where he went to purchase machinery for a 100-stamp mill to be erected on the mine. The mill was purchased from Frazer & Chalmers, of Chicago, and the iron and steel alone weigh 735,000 pounds. The material, including lumber and other material, consists of 150,000 pounds. Shipment of it will commence in about two weeks. A mammoth boiler and engine have also been procured, for the motive power will be steam for awhile. Later it is the intention of the company to have water power. Mr. Gillingham will leave for the mine with a large force of men to begin preparing the ground for the big stamp mill. It has always been a difficult matter to get machinery to reduce the ore of the Phoenix mine cheap enough to handle it profitably. The new Marshall mills were supposed to be just the thing, but were found inadequate and had to be discarded.

The latest improved stamp mill cannot very well be improved on, and, acting on his good judgment, Mr. Gillingham urged his company to purchase the material and at once erect a stamp mill that can treat enough ore at a time to run the profits up to a paying basis. It begins to look like the old mine would yet be operated successfully.

BRITISH COLUMBIA.

HYDRAULIC MINING.—*Nelson Miner*, June 10: Several stockholders of the Van Winkle Hydraulic Mining Co. were in Lytton last week, in expectation of seeing the first clean-up. There was not a sufficient volume of water, however, and the first wash-up will probably be witnessed this week. Among those in the party were J. M. Buxton, R. G. Tatlow, Edw. Mahon, Geo. DeWolf, H. E. Newton and Mining Engineer J. B. Hobson. The Van Winkle Co. has a subscribed capital of \$500,000, divided into 50,000 shares. They have constructed a ditch four miles in length and put in 3000 feet of 22-inch steel pipe, which gives them 375 feet head of water. One 8-inch monitor is ready for operation and a second one will be put in shortly. The dirt shows a good average, and when the present hydraulic apparatus is working it is estimated that 2500 yards can be easily worked in a day. The Lytton claim, immediately adjoining the Van Winkle, also shows every indication of wealth. A shaft is being sunk to a depth of 500 feet, and as high as \$5 in gold has been washed out of one cubic yard of dirt. Development work on this claim will be pushed forward during the summer. The Fraser, just across the river from the Van Winkle, is also a promising claim. Engineer Hobson has gone up to the Cariboo country to superintend the construction of hydraulic works on the Horsely placer claim, which is owned entirely by Canadian Pacific officials, Messrs. VanHorne and Abbott being largely interested.

THE SALMON RIVER CLAIMS.—J. Brigman, who has been spending a few days in Nelson, gives a very encouraging account of the outlook on the Salmon. Several hydraulic claims have been secured near the mouth of the Salmon river, and all of these give indications of becoming paying producers as soon as properly opened. Water is easily reached within a mile, and can be put on the ground very conveniently. Some Spokane capitalists have become interested with Mr. Brigman, and in conjunction with him they have purchased a portion of the Bates Bros.' claim, which will be needed in opening up their own ground. Careful prospecting has developed the fact that most of these claims will average from one cent per pan, and from the ease with which they can be worked will yield large returns. There is a large amount of ground along the river which was worked some 20 years ago, but abandoned owing to high prices for labor and supplies and lack of adequate means to work them properly. These can now be taken up and made to pay well. The coming summer will no doubt see a revival of placer and hydraulic work along the Salmon and its tributaries.

OREGON.

PROSPECTORS.—*Jacksonville Times*, June 16: Jackson and Josephine counties are still full of prospectors. Geo. Jensen, who is running a tunnel for the Jacksonville Milling and Mining Co., thinks that the main ledge will soon be struck. A. W. Sturges has 12 men employed at his extensive mines in Forest creek, and will make a clean-up by the 1st prox, which will astonish the natives. The Ashland Mining Co. has procured a Burleigh diamond drill to hasten operations in the bard rock in which they are now working, and will be in use after the first of July. Geo. Schump's ledge in Willows Springs precinct has been put in good shape and looks better than ever. Many of the placer-miners have finished for the season, but the majority are engaged in cleaning up or preparing to. The output of gold dust will be larger this season than it has been for many years past. Thos. Hammersley, of Gold Hill, who made an important discovery in Jump-off-Joe district, has sold half his ledge to Messrs. Lewis & Kinney, of Portland, for \$1000. They will develop it immediately. A very promising ledge has been discovered in Humboldt district by Henry D. Kubli and Ben. Thurston, and it promises to be a permanent vein. Some of the ore was sent to K. Kubli, and it certainly is among the richest we ever saw. Ore crushing will begin at the Fitch & Davis mine, called the Comstock of Oregon, before another month goes by, the machinery being already at the ground. The work of getting the mill up the mountain was immense, and several men were injured in the undertaking.

THE BAILEY BROS.' FIND.—*Bedrock Democrat*, June 12: The showing being made by the Mahel mine, Bailey Bros.' find, in the White Swan district, east of Baker City, is such as to warrant the statement that its equal in richness has never been found in the northwest, and in saying this the *Democrat* feels that it is even drawing the facts mildly. Since the discovery May 1st last, the mine has been in the course of development by the sinking of a shaft, and at this time the shaft is down over 40 feet, and, as well known to many mining men, the five-foot vein of ore continues all the way down and shows every evidence of permanency. Up to this time the amount of ore sacked during the progress of work will yield, as estimated conservatively by mining men, somewhere between \$50,000 and \$60,000, while on the dump the remainder of the ore will go \$100 to the ton. On Wednesday evening last, while sinking operations were in progress in the shaft and at a depth of 40 feet, a huge quartz howler in the bottom was run on to, and it became necessary to put in several "shots" to dislodge the deposit of ore. This was done, and when the smoke cleared away and the miners returned down the shaft, pieces of gold were scattered in every direction, and \$500 or more were picked up. The heavier pieces of quartz impregnated with gold were placed in sacks and piled with the already great accumulation of wealth awaiting mill reduction. Such a revelation of wealth is so astounding that it seems impossible of belief, but these are facts and are ready of substantiation. From the first mention of this find, the *Democrat* has been careful lest its readers might be suspicious of exaggeration, but the facts in this case cannot be overdrawn and have not in any particular in previous "write-ups" of the Bailey discovery. Its wealth in gold deposits is beyond comparison with anything of the kind ever discovered, and, if located in the State of Colorado, would bring 10,000 people to the scene in 60 days. Samples of the ore from the 40-foot depth in the shaft of the Mahel

mine can be seen on exhibition at the Baker City National Bank. The samples were brought in yesterday by Mr. Sam Baisley, and all of them show large quantities of gold. After the "shots," over 100 pounds of ore such as the pieces brought in were placed in the sacks, besides much more yet remaining when work for the day was stopped.

List of U. S. Patents for Pacific Coast Inventors.

Reported by Dewey & Co., Pioneer Patent Solicitors for Pacific Coast.

FOR THE WEEK ENDING JUNE 13, 1893.

499,415.—CULTIVATOR—Cardinal & Love, Newcastle, Wash.
499,517.—CONDUCTOR'S INDICATOR—B. W. Carpenter, Hesper, Or.

23,640.—DESIGN FOR LAMP STOVES—J. F. Myers, S. F.

The following brief list by telegraph, for June 20, will appear more complete on receipt of mail advices:

California—James C. Wood, Los Angeles, bed lounge; James A. Lighthouse, San Francisco, coin machine; Bernard W. McKenzie, San Diego, hose-fastener; Isaac S. Goldman, Los Angeles, hose band; James H. Jones, San Francisco, rotary fan; Francis S. Jerome, San Francisco, trunk; Milton A. Wheaton, San Francisco, can-heading machine; Richard N. Brooks, San Francisco, rotating index; Lewis Peterson, San Francisco, advertising machine; Norton H. Pine, Eureka, rope-leader for winding drums; Arthur Reynolds, San Francisco, animal shears; Juan F. Santellana, San Francisco, leveling and measuring telemeter; James C. Wood, Los Angeles, bed chair; John M. Finch, Marysville, separator; Ellis A. Mosser and E. J. Cox, Riverside, ladder; August Fitch, Los Angeles, reversible plow; Frederick O. Norton, Oroville, secondary battery; Charles L. Logan, Los Angeles, fare register.

Oregon—Owen H. Dabney, Salem, cane stool; Carl M. Kardell, Marshfield, saw-setting device; Carl Hoffman, Roseburg, receptacle for growing plants.

Washington—Alfred Williams, Seattle, filter; Geo. N. Peck, Tacoma, school seat and desk; Richard Nash, Tacoma, car coupling.

Note.—Copies of U. S. and Foreign patents furnished by Dewey & Co. in the shortest time possible (by mail telegraphic order). American and Foreign patents obtained, and general patent business for Pacific Coast inventors transacted with perfect security, at reasonable rates, and in the shortest possible time.

Mining Share Market.

Although the last weekly reports from the Comstock mines are quite encouraging in their nature, especially with regard to the Middle and North End mines, they have not had much effect on the prices. There seems to be little interest in the market, what attention there is given to it being upon a few mines. In most of them the transactions are comparatively light.

Ore shipments of 500 or 600 tons of gold-bearing rock have been made from the Crown Point to Mexican mill, to make a test run of the Frue concentrators recently put in at the mill. The rock is of low grade, and if the test is satisfactory more rock of the same class will be worked. At the Potosi the bunches of ore continue to look well. Ore shipments to the Nevada mill have been increased and the company should be able to work out of debt in a very short time, as the grade of ore is better, and with the air connection made the ventilation will be so improved that a greater quantity of ore can be extracted without increasing the expense.

At the annual meeting of the stockholders of the Bodie Con. 54,512 shares were represented and the following officers were elected for the ensuing year: H. D. Walker, president; L. Osborn, vice-president; and A. Herrmann, W. H. King, R. H. Sinton, E. P. Danforth and John W. Kelly, directors. M. E. Willis was elected secretary and John W. Kelly, superintendent. The secretary's financial statement showed a credit of \$9061.41.

A review of the milling work of the Standard mine at Bodie is given in another column, and will be found of interest to millmen who are banding ores, concentrates or tailings.

Market Reports.

The Markets.

SAN FRANCISCO, June 22, 1893.

The Metals.

Tin has continued to manifest strength during the week and has steadily advanced. Copper is weaker. There is no change in lead.

San Francisco Metal and Coal Market.

Copper Trade.

Henry R. Merton & Co. report the stock of Copper in England and France and afloat thereto from Australia and Chili on the 1st of June, as follows:

	Price.	Tons.
1891.	£55 5s od	58,258
1892.	46 7 6	53,065
1893.	43 2 6	49,951

The exports of Copper from New York for the first four months of the year were 11,618 tons matte and 11,351,800 lbs. refined, valued at \$24,426,900. On the 10th Copper was quoted in London at £44 7s 6d.

Sales of Silver.

There were only two offers to sell Silver to the Government on the 12th. One of these was at \$3.60 and the other at \$3.39. The acting Director of the Mint thought there was too much difference between the two proposals, and made and offer of \$3.40. He secured 368,000 ounces at that figure, which is 6-10 below the London parity. Fine Silver is now 38 1/2 d in London, an advance of 1/2 d since the 1st inst. The improved price is the result of

lessened offerings. The demand, both at home and abroad, shows no improvement. Some mines, however, have been closed, and others are yielding less than formerly.

Silver on the Block.

Secretary Morton, according to the New York Post's Washington correspondent, since his return from the West has urged upon Secretary Carlisle the expediency of selling a lot of our store of pig silver for what we can get for it and turning the proceeds into the treasury. Carlisle responds that there is no law under which he could make such sales.

NEW YORK, June 21.—Following are the closing prices for the week:

	Silver in—	Copper.	Lead.	Tin.
Thursday	38 1/2	83 1/2	10 60	3 70
Friday	38 1/2	83 1/2	10 60	3 62 1/2

DIVIDEND NOTICE.

SAN FRANCISCO SAVINGS UNION,
536 California Street, corner Pansome.
Branch, 1700 Market Street, corner Polk.

For the half year ending with 30th of June, 1893, a dividend has been declared at the rate of five (5) per cent per annum on Term Deposits and four and one-sixth (4 1/6) per cent per annum on Ordinary Deposits, free of taxes, payable on and after Saturday, July 1, 1893.
LOVELL WHITE, Cashier.

DIVIDEND NOTICE.

THE GERMAN SAVINGS & LOAN SOCIETY
526 California Street.

For the half year ending June 30, 1893, a dividend has been declared at the rate of five and one-tenth (5 1/10) per cent per annum on Term Deposits, and four and one-quarter (4 1/4) per cent per annum on Ordinary Deposits, payable on and after Saturday, July 1, 1893.
GEO. TOLNEY, Secretary.

WELL MACH'Y

All Kinds, Water, Gas, Oil, Mining, Ditching, Pumping, Wind and Steam Heating Boilers, &c. Will send you to send 25c. for Encyclopedia of 1500 Engravings. The American Well Works, Aurora, Ill., also, Chicago, Ill.; Dallas, Tex.; Sydney, N. S. W.

WORLD'S FAIR REDUCTION.

San Francisco Pioneer Screen Works
JOHN W. QUICK, Proprietor.

GREAT REDUCTION IN MINING SCREENS UNTIL the opening of the World's Fair. Perforated Sheet Metal, Steel, Russia Iron, Zinc, Copper, Brass, Etc. MINING SCREENS A SPECIALTY.
221 & 223 First St., San Francisco.

QUARTZ SCREENS

A specialty. Round, slot or burr slot holes. Genuine Russia Iron, Homogeneous Steel, Cast Steel or American planished Iron.

Zinc, Copper or Brass Screens for all purposes. California Perforating Screen Co., 145 & 147 Beale St., S. F.

PRACTICAL TREATISE ON HYDRAULIC MINING.

By AUG. J. BOWIE, JR.

This new and important book is on the use and construction of Ditching, Flumes, Dams, Pipes, Flow of Water on Heavy Grades, methods of mining shallow and deep placers, history and development of mines, records of gold washing, mechanical appliances, such as nozzles, surdy-gurdy, rockers, and arrastra, etc.; also describes methods of blasting; tunnels and sluices; tailings and dump; duty of miners' inch, etc. A very practical work for gold miners and users of water. Price, \$5, post-paid. For Sale by DEWEY PUBLISHING CO., 220 Market St., San Francisco, Cal.
